About This Book

This book provides application developers with complete information about writing their own diagnostic applications or service aids for the AIX® operating system. Programmers can use this book to gain knowledge of the hardware diagnostic subsystem and the databases used to perform hardware diagnostics. Topics include operating environments, diagnostic components, features and packaging, debugging hints, and code examples.

Content of This Book

This edition of this book contains no technical changes. The content is identical to the previous edition.

Highlighting

The following highlighting conventions are used in this guide:

**Bold** Identifies commands, subroutines, keywords, files, structures, directories, and other items whose names are predefined by the system.

*italics* Identifies parameters whose actual names or values are to be supplied by the user.

`monospace` Identifies examples of specific data values, examples of text similar to what you might see displayed, examples of portions of program code similar to what you might write as a programmer, messages from the system, or information you should actually type.

Case-Sensitivity in AIX

Everything in the AIX operating system is case-sensitive, which means that it distinguishes between uppercase and lowercase letters. For example, you can use the `ls` command to list files. If you type `LS`, the system responds that the command is “not found.” Likewise, `FILEA`, `FiLea`, and `filea` are three distinct file names, even if they reside in the same directory. To avoid causing undesirable actions to be performed, always ensure that you use the correct case.

ISO 9000

ISO 9000 registered quality systems were used in the development and manufacturing of this product.

Prerequisite Software

For the POWER-based platform, the `bos.diag` 4.3.3+ package is required.

For the Itanium-based platform, the `bos.diag` 5.1.0 package is required.
Chapter 1. Introduction

This chapter contains the following topics:

- Structure
- Strategy
- Diagnostic Commands

The Structure section gives an overview of the diagnostic system. Key application modules are described and their relationships to one another is shown.

Also, a figure is displayed that shows the relationship between the Diagnostic Controller, Diagnostic Applications, and Application Test Units.

The Strategy section gives an overview of the strategy used by the diagnostic system to discover and analyze problems on the system.

The Diagnostic Commands section gives the usage and command line flags for the diag and diagrpt commands.
Structure of Diagnostics

The Diagnostic System is a collection of application modules that work together to perform some software or hardware action. This collection of application modules are comprised of various distinct components.

The following figure illustrates the diagnostic architecture:

The architecture shows that the Diagnostic Controller has two main functions:

• Resource Selection
• Task Selection

Tasks are operations that can be performed on a resource. Running Diagnostics, Displaying VPD, or Formatting a Resource, are examples of tasks. Service aids are also considered as tasks.

Resources are devices contained by the system unit. The diskette drive and CD ROM drive are examples of resources.

The Function Selection Menu contains selections allowing either resources or tasks to be displayed. When Task Selection is made and a task has been selected, a list of resources supporting that task is displayed. Alternatively, when Resource Selection is made, and a resource or group of resources are selected, then a list of tasks supporting the selected resources is displayed.
A Diagnostic Application or Task may involve the use of Application Test Unit code, which in turn may involve the use of a Diagnostic Kernel Extension or a Device Driver to gain access to the hardware.

The figure below illustrates the current diagnostic structure that allows access to diagnostic function concurrent with system operation. Diagnostics for a given resource consists of an executable file containing Diagnostic Application code, which controls the execution of one or more Application Test Units. This executable is started by the Diagnostic Controller, which allows the user to select diagnostic modes and devices to test. To properly execute the Application Test Units, the Diagnostic Application currently must have detailed specific knowledge about each of the Application Test Units.

The `execu()` interface is the call interface for Application Test Units, and contains all the information necessary to run the Application Test Unit against a particular device and return results. PDiagex is a special generic device driver written for use by Application Test Units, which can be used in place of the functional device driver to provide a simple direct interface to the device under test. Doing so places a greater requirement on the Application Test Unit to directly manipulate the device hardware, but in doing so, it provides earlier use of the Application Test Unit during the hardware bring-up and debug phase, since the Application Test Unit is not dependent on the availability of a working functional device driver.

### Strategy for Diagnostics

The strategy for diagnostics is founded on:

- Staging diagnostics based on underlying hardware capabilities according to three levels of testing:
  - Shared
  - Subtest
  - Full-test
- Isolating defective field replaceable units (FRUs) such that there is the least impact to the system. This is accomplished by either:
  - Option Checkout
  - System Checkout
Staging the Impact of Diagnostics

The impact of diagnostics is staged. There are three levels of tests supported by diagnostics:

**Shared**
The tests in this category are nondisruptive. Diagnostics does not need exclusive access to run these tests. All Diagnostic Applications (DA) should support the shared testing category since DAs perform error-log analysis. Other possible shared tests are error circuitry testing, cyclic redundancy checks of Loadable ROS, On Board Self Tests (provided the appropriate recovery procedures are included), and selected functional testing such as diagnostic reads and writes.

**Subtest**
The tests in this category apply to multiplexed resources such as Native I/O Planar and multiport async cards. The sub-tests are disruptive, but only to a portion of the resource. To run these tests, diagnostics needs exclusive access to the portion of the resource that is being tested.

**Full-test**
The tests in this category impact the entire resource. Diagnostics must have exclusive access to the entire resource to run these tests.

Option Checkout

If the configuration is viewed as a tree structure, diagnostics starts testing at the leaves of the tree, and moves vertically and horizontally down the tree toward the root. The leaves represent terminal devices, and the root is the processor.

The following algorithm generally describes the isolation strategy. It starts at an arbitrary node in the tree and isolates to the correct FRU bucket based on the good or bad status of siblings and parent resources.

The steps are:
1. Test resource \( x \). If no problems are detected, no further isolation is required.
2. Test a sibling of resource \( x \), called resource \( y \). If no problems are found, the fault of resource \( x \) is isolated to resource \( y \).
3. Test the parent of resources \( x \) and \( y \). If no problems are detected, the problem has not been isolated to a single failing resource. The FRU buckets associated with resources \( x \) and \( y \) will both be reported. No further isolation is required. However, if the parent fails its tests, disregard the failures of resources \( x \) and \( y \) and continue isolating the problem for the parent.

This general process of testing siblings and parents is repeated until a resource passes its tests or until a DA indicates that no further testing is required.

The diagnostic subsystem attempts to isolate to a single failing device. When multiple child devices fail their tests, the fault most likely lies with the parent. Thus the DA testing the parent in step 3 should name the parent as being defective and indicate that no more devices should be tested, in which case the diagnostic controller would only report the parent. The status of the child devices that have been tested is identified in the DA's control block.

System Checkout

Each resource in the system that has not been deleted from the resource selection list is tested during system checkout. System Checkout selection is accomplished by selecting All Resources from the [Resource Selection] Menu. User interaction is not allowed unless a problem has been detected and a question needs to be asked to isolate the problem.

Configuration processing for system checkout is different from that for option checkout, which impacts the effectiveness of the FRU Callout. Option checkout is the specification of an individual resource to test. When option checkout is chosen, the option chosen is tested first, and if a problem is found, it is traced back through its siblings and parents until it has been isolated. The configuration is processed from the outside in. When system checkout is chosen, the configuration is processed from the inside out. For example, the configuration is processed starting with the system planar, and works its way out on a
per-card basis. First a card is tested, then the devices attached to the card are tested, and then the devices attached to the device attached to the card are tested, and so on. This process is repeated for each card attached to the system planar.

Option Checkout is more effective because the children are tested before the parent, which allows the parent to determine its own culpability above and beyond its own test results. The parent can implicate itself for no other reason than that its children are failing.

**Diagnostic Commands**

This chapter describes the commands available in the Diagnostic Subsystem.

- **diag Command**
- **diagrpt Command**

**diag Command**

The `diag` command performs hardware problem determination. When you suspect there is a problem, `diag` assists you in finding it. The command has the following syntax:

```
diag [ -a ] | [ -s [ -c ] | [ -E days ] | [ -e ] | [ -d Device | -c ] | [ -v ] | [ -e ] | [ -A ] ] | [ -B | -c ] | [ -T taskname ] | [ -S testsuite ] | [ -c -d Device -L pending | complete ]
```

Most users should enter the `diag` command without any flags. The following flags perform various actions:

- **-A** Advanced mode. Default is non-advanced mode.
- **-a** Processes the changes in the hardware configuration. For example, missing and/or new resources.
- **-B** Tests the base system devices, such as planar, memory, processor.
- **-c** Indicates that the machine will not be attended. No questions will be asked. Results are written to standard output. Normally used by shell scripts.
- **-d Device** Names the resource that should be tested. The `Device` parameter is a resource name displayed by the `lscfg` command.
- **-E Days** Number of days used to search the error log.
- **-e** Causes the device's Diagnostic Application to be run in Error Log Analysis mode.
- **-L pending | complete** Log Repair Action for a resource specified with the `-d` and `-c` flags. Use `pending` if the part has been replaced, but it is not yet known if this part will remain in the system. Use `complete` if the part has been replaced and it is known that this part will remain in the system.
- **-S testsuite** Tests the Test Suite Group:
  1. Base System
  2. I/O Devices
  3. Async Devices
  4. Graphics Devices
  5. SCSI Devices
  6. Storage Devices
  7. Commo Devices
  8. Multimedia Devices
- **-s** Causes the system to be tested in System Checkout mode.
- **-T taskstring** Specifies a particular Task to execute. The `taskstring` depends on the particular task to be executed. See Tasks for more information.
- **-v** System Verification Mode. Default is Problem Determination mode.
**diagrpt Command**

Displays the conclusions made by diagnostics. The `diagrpt` command has the following syntax:

```
/usr/lpp/diagnostics/bin/diagrpt [ [ -o ] | [ -s mmddyy ] | [ -a ] | [ -r ] ]
```

The `diagrpt` command reports the conclusions made by diagnostics.

If the user does not specify a flag, a scrollable menu with all diagnostic conclusion reports is displayed.

- `-o` Displays the latest diagnostic conclusion.
- `-s mmddyy` Reports diagnostic conclusions made after the date specified (`mmddyy`).
- `-a` Displays the long version of the Diagnostic Event Log.
- `-r` Displays the short version of the Diagnostic Event Log.
Chapter 2. Operating Environments

This chapter contains the following topics:

- Online Diagnostics
- Standalone Diagnostics
- NIM Diagnostics

The Diagnostics operating environment consists of online and standalone diagnostics. The two environments differ in the way they are packaged, installed, and executed. Diagnostics is a collection of applications, the majority of which are device specific. These applications are packaged as filesets, with each fileset associated with a device.

Online diagnostics is commonly referred to as running diagnostics from an installed hardfile. This implies that the operating system, and the various device related packages have been installed.

Standalone diagnostics are packaged on removable media. The removable media contains the operating system, and all device related applications, device drivers, ODM stanzas, etc. supported at a particular release level. Third party devices and other devices not available for inclusion on the removable media at release time are supported by Diagnostic Supplemental Media.

Hardware Diagnostics can also be performed on NIM clients using a diagnostic boot image from a NIM server, rather than booting from removable media or hardfile. Not only does this eliminate the need for diagnostic boot media, it eliminates the need to have diagnostics installed on the local hardfiles of the client machines.

Diagnostics are a secure application. The user must know the appropriate password to run diagnostics. Diagnostics are inherently destructive, but this destructiveness is managed. The run-time status of each device identifies the level of diagnostics that can be safely executed. In addition, the testing has been structured so that some tests can only be executed in standalone mode.

Online Diagnostics

Online diagnostics can be run in three modes:

- **Concurrent Mode**
  - Allows the normal system functions to continue while selected resources are being checked.
- **Service Mode**
  - Allows checking of most system resources.
- **Maintenance Mode**
  - Allows checking of most system resources.

Concurrent Mode

Concurrent mode provides a way to run online diagnostics on some of the system resources while the system is running normal system activity. Because the system is running in normal operation, devices such as the following may require additional actions by the user or diagnostic application before testing can be done.

- SCSI adapters connected to paging devices
- Disk drive(s) used for paging, or are part of the rootvg
- LFT devices and graphic adapters if a Windowing system is active
- Memory
- Processor
Service Mode

Service mode provides the most complete checkout of the system resources. This mode also requires that no other programs be running on the system. All system resources, except the SCSI adapter and the disk drives used for paging, can be tested. However, note that the memory and processor are only tested during Power On Self Tests (POSTs).

Service Mode is entered by booting the operating system in service mode.

Maintenance Mode

Maintenance mode provides the exact same test coverage as Service Mode. The difference between the two modes is the way they are invoked. Maintenance mode requires that all activity on the operating system be stopped.

The `shutdown -m` command is used to stop all activity on the operating system and put the operating system into maintenance mode. After setting the terminal type, use the `diag` command to start Diagnostics.

Standalone Diagnostics (POWER-based only)

Standalone diagnostics provide a method to test the system when the online diagnostics are not installed and a method of testing the disk drives that cannot be tested by the online diagnostics.

Standalone diagnostics are currently packaged on CDROM. They are run by placing the Standalone Diagnostic CDROM into the cdrom drive, then booting the system in service mode.

The Standalone Diagnostic CDROM file system is mounted over a RAM-file system for execution. Because of this, the CDROM drive (and the SCSI controller that controls it) cannot be tested by the standalone diagnostics.

Device support that is not on the Diagnostic CDROM must be supported by Diagnostic Supplemental Media.

Tasks not Supported in Standalone Diagnostics

Some tasks and service aids are not supported in standalone diagnostics. This is due to the fact that Standalone diagnostics runs from a RAM-file system, they have no direct access to the hardfile.

See the Diagnostic Task Matrix for the list of supported tasks and their operating environments.

Console Configuration Diskette

The Standalone Diagnostic Package allows the use of a Console Configuration Diskette to accomplish two tasks:

- Use a Different Async Terminal as the Console
- Set the Refresh rate on a High-Function Terminal

The Create Customized Configuration Diskette task allows this diskette to be created.

Different Async Terminal for Console

The Standalone Diagnostic Package allows a terminal attached to any RS232 or RS422 adapter to be selected as a console device. The default device is an RS232 tty attached to the first native serial port. However, a file is provided allowing the console device to be changed. The file name is `/etc/consdef`. The format of the file is:

```bash
# COMPONENT_NAME: (cfgmeth) Device Configuration Methods
#
# FUNCTIONS: consdef
#
# ORIGINS: 27, 28
```
The console definition file is used for defining async terminal devices, which are the console candidates at system boot. During system boot, all natively attached graphic displays, any async terminal on native serial port s1, and async terminals defined in this file will display the "Select System Console" message. Only one terminal may be selected as console. If the terminal attributes are not specified in this file, default values from the odm database are assumed. However, the location and connection attributes are mandatory. The location value may be displayed with the lsdev command.

The entries must be in the following format:

```
#ALTTTY:
  connection=value
  location=nn-nn-ss-nn
  attribute=value
  ...
#ALTTTY:
  connection=value
  location=nn-nn-ss-nn
  attribute=value
  ...
```

Lines in this file must not exceed 80 characters. All comments must be preceded by a pound sign (#) in the first column.

For backward compatibility, the "ALTTTY:" keyword is not required for the first entry.

For example, to display the console selection message on the ttys attached to the S1 and S2 ports, uncomment the following stanzas:

```
#ALTTTY:
  connection=rs232
  location=00-00-S1-00
  speed=9600
  bpc=8
  stops=1
  xon=yes
  parity=none
  term=ibm3163
#ALTTTY:
  connection=rs232
  location=00-00-S2-00
  speed=9600
  bpc=8
  stops=1
  xon=yes
  parity=none
  term=ibm3151
```

High-Function Terminals 60/77-Mhz Refresh Rate

Certain high-function terminals may be set to run at a different refresh rate. The Console Configuration Diskette may be created setting the appropriate refresh rate for the terminal used as the console. The Standalone Diagnostic Package uses the default 60-Mhz rate. The Create Customized Configuration Diskette task allows this value to be changed, and a new Console Configuration Diskette to be created.
NIM Diagnostics

Hardware diagnostics can be performed on all NIM clients using a diagnostic boot image from a NIM server, rather than booting from removable media or hard disk. This is useful for standalone clients, because the diagnostics do not have to be installed on the local hardfile. Diagnostic support comes from a SPOT resource.

In addition, diskless and dataless clients have another way of loading diagnostics from the network. You can boot a diskless or dataless client from the network the same way you do for normal use, but with the machine’s key mode switch in the Service position. If the client’s key mode switch is in the Service position at the end of the boot process, hardware diagnostics from the server’s SPOT are loaded. If a standalone client boots with the key in the Service position, the diagnostics (if installed) are loaded from the hard disk.

Running diagnostics in a NIM environment is very similar to running in Standalone mode.

See [Installing AIX](#) for more information on the NIM environment.
Chapter 3. Diagnostic Components

This chapter contains information on the various components that make up the Diagnostic Subsystem environment.

- Diagnostic Controller
- Diagnostic Applications
- Tasks & Service Aids
- Application Test Units
- Diagnostic Kernel Extension
- Diagnostic Library
- Diagnostic Object Classes
- Diagnostic Header Files
- User Interface
- Diagnostic Menu Examples

Diagnostic Controller

The Diagnostic Controller function is started when the root user enters the `diag` command. Various flags that allow operations to be performed directly may be specified as input. For example, a flag may specify that the system or a particular resource is to be tested or that the system is to be run unattended. If no flags are specified, then the Diagnostic Controller presents menus to determine what the user wants to do.

Diagnostic object classes define the resources and tasks available for the Diagnostic Controller to work with. Predefined data in these object classes specify various attributes about the resources and tasks that may be available on the system.

The Customized Device object class (CuDv) contains information describing the resource instances actually defined to the system. A defined resource instance may or may not have a corresponding device driver that is used to control it. A resource may be a rack, drawer, adapter, disk, memory card, floating point chip, planar, bus, and so on.

The Diagnostic Controller is a data-driven program. It uses information found in both the CuDv and the Predefined Diagnostic Resources object class (PDiagRes) to generate a list of supported resources. This list of supported resources is used to build the Resource Selection menu.

The Diagnostic Controller supports dynamic reconfiguration of processors by updating the Resource Selection menu if a reconfiguration operation occurs while the diagnostic controller is running.

Given the user’s selection from the Resource Selection Menu, the Diagnostic Controller employs the PDiagRes object class to determine the appropriate Diagnostic Application (DA) to start. The Diagnostic Controller waits for the DA to complete. Diagnostic Application status is returned by the exit system call.

The Diagnostic Controller employs a system-wide view of the configuration enabling the Diagnostic Controller to walk through the configuration database testing resources. For example, if a resource fails its tests, the Diagnostic Controller may attempt to test other resources until the problem has been isolated. The Diagnostic Controller understands the dependencies between the resources. The term “resource” is used in a generic sense and includes adapters, as well as terminal devices.

The Diagnostic Controller analyzes the conclusions made by the Diagnostic Applications and generates a Problem Report. The Problem Report lists the field replaceable units (FRUs) that should be replaced, the probability of failure associated with each FRU, and the reason why the diagnosis was made.
The Diagnostic Controller writes its analysis to the directory `/etc/lpp/diagnostics/data`, and the `diagpt` command, or the "Display Previous Diagnostic Results" task, can be used at a later date to retrieve these results.

In addition, notification of problems can be sent to external programs registered with the Diagnostic Controller. The registration is by ODM objects in the `PDiagAtt` class. There are 2 possible registrations:

**For Systems attached to a Hardware Management Console:**

```
PDiagAtt:
   DType = <fileset nickname>
   DSClass = ""
   attribute = "notify_service"
   value = ""
   rep = "s"
   DClass = ""
   DApp = /usr/lpp/diagnostics/bin/diagServiceEvent
```

The program specified in `DApp` of the `notify_service` attribute is invoked when the system is managed by a Hardware Management Console (HMC). The program is invoked with the diagnostic event log sequence number of the diagnostic conclusion. The diagnostic event log API can be used to extract the specific data of the diagnostic analysis and perform any customized notifications.

The `<fileset nickname>` is any 15 character (or less) string that represents which fileset ships this stanza. Diagnostics does not use the nickname, but a unique value per fileset is required in `DType` to facilitate installing and updating the attribute because the same attribute name can be shipped in other filesets. For example, fileset `devices.chrp.base.diag` would ship a stanza like:

```
PDiagAtt:
   DType = "DevChrBasDia"
   DSClass = ""
   attribute = "notify_service"
   value = ""
   rep = "s"
   DClass = ""
   DApp = /usr/lpp/diagnostics/bin/diagServiceEvent
```

**For Systems not attached to a Hardware Management Console:**

```
PDiagAtt:
   DType = <fileset nickname>
   DSClass = ""
   attribute = "notify_extern"
   value = ""
   rep = "s"
   DClass = ""
   DApp = <complete path to external notification program>
```

The program specified in `DApp` of the `notify_extern` attribute is invoked when the system is not managed by a Hardware Management Console (HMC). The program is invoked with the diagnostic event log sequence number of the diagnostic conclusion. The diagnostic event log API can be used to extract the specific data of the diagnostic analysis and perform any customized notifications.

The `<fileset nickname>` is any 15 character (or less) string that represents which fileset ships this stanza. Diagnostics does not use the nickname, but a unique value, per fileset, is required in `DType` to facilitate installing and updating the attribute because the same attribute name can be shipped in other filesets. For example, fileset `devices.chrp.base.diag` would ship a stanza like:

```
PDiagAtt:
   DType = "DevChrBasDia"
   DSClass = ""
   attribute = "notify_extern"
   value = ""
```
Control Flow of the Diagnostic Controller

Invoking the `diag` command without any flags starts the Diagnostic Controller which performs the following:

1. Displays the **Operating Instructions** menu. The version number will reflect the version of the Diagnostic code installed.
2. Displays the **Function Selection** menu, and starts the command associated with the user's selection.

Invoking the `diag` command with flags starts the Diagnostic Controller and passes the flags on to the Controller.

The Diagnostic Controller performs the following tasks:

1. Initialize the user interface. It is assumed that if there is no display and keyboard, then the initialization will fail.
   - If `-a`, then performs configuration management.
   - If `-s`, then performs system checkout once.
   - If `-S#`, then runs diagnostics on the resources indicated by the Test Suite ID.
   - If a flag was not specified, Diagnostics prompts the user.
2. From the **Function Selection** Menu, allows the user to select one of the following:
   - Select **Diagnostics**
   - Select **Advanced Diagnostics**
   - Select **Task Selection Menu**
   - Select **Resource Selection Menu**
3. If **Diagnostics** or **Advanced Diagnostics** is selected, then the following happens:
   - The **Diagnostic Mode Selection** menu is displayed, to determine if **System Verification** or **Problem Determination** should be run.
   - If **Problem Determination** is chosen, then the Diagnostic Controller automatically scans the error log for any PERMANENT HARDWARE errors that have been logged within the last 7 days to determine if any devices should be automatically tested. A problem report may be generated.
   - Walks the configuration database to determine which resources in the current configuration can be tested. This information is presented in the **Resource Selection Menu**.
   - If **Advanced Diagnostics Routines** is chosen, and the system is in **Online Service** mode of operation, the Diagnostic Controller will display the **Test Method** menu to determine if the tests should be repeated.
   - Initializes the input parameters to the Diagnostic Application (DA), which are contained in the **TMInput - Test Mode Input** object class.
   - Runs the **Diagnostic Application** (DA) of the resource to be tested.
   - Waits for the DA to complete.
   - The Diagnostic Controller then:
     - Performs isolation process.
     - Presents conclusions to the screen.
     - If no trouble is found, diagnostics exits with a return value of 0. Otherwise, a value of 1 is returned if the hardware was tested bad.
4. If **Task Selection Menu** is selected, then the following happens:
   - The Diagnostic Controller displays a list of Tasks that are available for the system.
• After a task has been selected, a Resource Selection Menu appears if the selected task supports a resource selection. After selection of a Resource, the task is called with the selected resource name as a command-line argument.

• If the selected task does not support resource selection, then the task is invoked.

5. If Resource Selection Menu is selected, then the following happens:
   • The Diagnostic Controller displays a list of Resources available on the system.
   • After a Resource has been selected, a Task Selection Menu will appear containing the commonly supported tasks for each selected Resource. After selection of a task, the task is invoked.

Return Status
The Diagnostic Controller returns the following values:

<table>
<thead>
<tr>
<th>Diagnostic Controller</th>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIAG_EXIT_GOOD</td>
<td>0</td>
<td>No problems found</td>
</tr>
<tr>
<td>DIAG_EXIT_DEVICE_ERROR</td>
<td>1</td>
<td>Error running diagnostics</td>
</tr>
<tr>
<td>DIAG_EXIT_INTERRUPT</td>
<td>2</td>
<td>Received an interrupt while running diagnostics</td>
</tr>
<tr>
<td>DIAG_EXIT_NO_DEVICE</td>
<td>3</td>
<td>Device to test was not found in system configuration</td>
</tr>
<tr>

<td>DIAG_EXIT_NO_AUTHORIZATION</td>
<td>12</td>
<td>User is not authorized to run diagnostics</td>
</tr>
<tr>
<td>DIAG_EXIT_KERNSUPPORT</td>
<td>13</td>
<td>Device is not supported on the 64-bit kernel</td>
</tr>
</tbody>
</table>

Diagnostic Applications

Note: The Diagnostic subsystem supports 32-bit diagnostic applications only.

Most resources in a system have a Diagnostic Application (DA), started by the Diagnostic Controller, that tests an area. DAs are associated with each resource supported by diagnostics in the configuration database.

DAs analyze the error log, display prompts and questions to the user, control which tests are run, call Application Test Units and analyze test results.

The following topics are discussed in detail:
• Device Configuration
• Determining the Level of Tests to Execute
• Drivers Used for Diagnostic Purposes
  – Production Driver Used for Diagnostic Purposes
  – Separate Diagnostic Driver Used for Diagnostic Purposes
  – Diagnostic Kernel Extension Used for Diagnostic Purposes
• Acquiring a Greater Share of the Resource
Device Configuration

In some cases, the DA will have to configure a device in order to test it. If the Configuration Method associated with the device does not contain the code that is required to load the device driver into the kernel and initialize it, then the DA performs this function.

However, in most cases, the DA may use one of the diagnostic library functions provided to perform the configuration. The following library functions aid in the configuration/unconfiguration process:

- `configure_device`
- `initial_state`
- `diagex_cfg_state`
- `diagex_initial_state`

If a resource is reconfigured, then it must be restored to its initial state before the DA exits. Also, never assume that the parent resource(s) are always configured.

Determining the Level of Tests to Execute

Each DA is responsible for determining the level of tests that can be safely executed. This determination is a function of how the underlying device drivers support access to the device.

For nonshared, nonmultiplexed devices, the DA should attempt to `open()` the device with read/write privileges and thus determine its access privileges. For shared or multiplexed devices, a more complicated strategy needs to be developed. Perhaps the simplest method - at least from an application standpoint - is to add support for an `openx()` system call to the device driver, where the `ext` parameter distinguishes between port-level and card-level diagnostics.

Drivers Used for Diagnostic Purposes

There are different scenarios for configuring a resource to test. Depending on the relationship the resource to be tested has with other resources, it may be desirable to use one method over another. For instance, to unconfigure a resource in order to load a separate diagnostic driver or kernel extension, it is necessary to unconfigure all of the children resources connected to the particular resource, if any. This could cause a problem if the child resources are in use. In this case, it is desirable to use the production driver for diagnostic purposes. In all cases, it is important to restore the resource (and child resources) to their original state after testing.

Production Driver Used for Diagnostic Purposes

If the resource is in the `DEFINED` state, the resource must be configured before testing. After the resource is configured, tests can be performed on the resource, and then the resource must be put back into its original state.
**Separate Diagnostic Driver Used for Diagnostic Purposes**

If the resource is in the **DEFINED** state, the diagnostic driver may be loaded for testing, then unloaded after testing. If the resource is in the **AVAILABLE** state because the production driver is loaded, it is necessary to unload the production driver, load the diagnostic driver, perform the tests, unload the diagnostic driver, and then reload the production driver. Any child resources must be unconfigured before the resource under test can be unconfigured.

**Diagnostic Kernel Extension Used for Diagnostic Purposes**

If the resource is in the **DEFINED** state, the resource must be put into the **DIAGNOSE** state for testing. If the resource is in the **AVAILABLE** state because the production driver is loaded, it is necessary to unconfigure the resource and all its children, reconfigure the resource into the **DIAGNOSE** state, test it, and then reconfigure the resource and all its children back to their original states.

**Acquiring a Greater Share of the Resource**

If further testing is required, then the DA should assist the user in determining if the user should proceed with the testing.

For some devices, it may be best to ask the user to switch to another window and vary the device offline before continuing. For others, it may be best to send software-terminate signals. And for still others, it may be best to start the commands that have been specifically provided to gracefully degrade the system.

**Error Log Analysis**

If the **dmode** field in the **TMInput** Test Mode Input, object class is set to either **DMODE_ELA** or **DMODE_PD**, then **Error Log Analysis** should be performed. Error log analysis should be considered a shared test.

The **getdainput** subroutine is used to get the test mode input parameters.

**resource_alias Attribute**

When a DA needs to analyze error logs from multiple resources, like the base system DA and system planar, memory and l2 cache resources, or a DA wants to analyze error logs that are logged against hardware events, like machine checks or environmental and power warnings (EPOW), then a PDiagAtt stanza must be used to define the alias between the device under test and the additional resources.

For example, the DA for the system planar on the RSPC platform performs error log analysis for machine checks that are logged by the RSPC Machine Check Error Handler. The following PDiagAtt stanza must be used to define the alias between the resource, sysplanar0, and the machine check event, MACHCHECK.

```plaintext
PDiagAtt:
  DClass = "planar"
  DSClass = "sys"
  DType = "sysplanar_rspc"
  attribute = "resource_alias"
  value = "MACHCHECK"
  rep = "n"
  DApp = ""
```

Thus, any error logged against "MACHCHECK" is analyzed by the DA for the resource of the class, subclass and type of "planar/sys/sysplanar_rspc", which is typically "sysplanar0". Any repair action done for the resource (sysplanar0) is associated with the error logged against "MACHCHECK".

Another example: The Diagnostic Application for the base system on the ChRP platform performs error log analysis for the firmware generated error logs for the system planar, memory and l2 cache resources. The following stanzas are used to invoke error log analysis from Problem Determination mode and to record the repair action in the error log after the system verification procedure.
**Enhanced Error Handling (EEH) Option**

EEH is an error-recovery mechanism for errors that occur during load and store operations on the PCI bus. EEH is made possible by EADS chips incorporated in newer POWER-based servers. In effect, each PCI slot on the EADS is its own PCI bus. This allows each adapter to be isolated (which is useful if PCI bus errors occur because error recovery can occur without affecting the operation of other adapters). Isolating the failing adapter prevents a faulty component from causing problems on the system and allows continued operation of other PCI devices during error recovery. Information about the faulty component and nature of the error (recoverable versus permanent) is logged in the AIX Error log.

The Diagnostics Application interface includes the `pdiag_set_eeh_option`, `pdiag_set_slot_reset`, and `pdiag_read_slot_reset` subroutines. These subroutines provide the DA with the necessary tools for adequate testing on the EEH option. The DA Support for this feature requires that the DA perform the following sequence of instructions in order:

1. Open I/O Adapter Test Units (TU_OPEN).
2. Call `pdiag_read_slot_reset` Verify that the EEH option is supported.
3. Execute full suite of Test Units (normal Test Units execution for affected component).
   - If an EEH error is reported and EEH is supported:
     - Call `pdiag_set_slot_reset`
     - Set the PCI slot to reset state (reset active) for the I/O adapter being tested.
     - Report EEH error.
   - If an EEH error is reported and EEH is not supported:
     - Report a software error

**Supported Devices**

Device Driver support for EEH is limited to the following devices that are supported by AIX 5L Version 5.2 with the 5200-01 Recommended Maintenance package:

- **Storage Adapters:**
  - Gigabit Fibre Channel
  - PCI SCSI RAID Devices
  - PCI Ultra SCSI Devices
  - PCI Dual Channel Ultra3 SCSI Adapter (6203) *
  - PCI Dual Channel Ultra2 SCSI Adapter (6205) *

- **Communications and connectivity (PCI bus type):**
  - Token-Ring PCI 4/16 Adapter (2920 and 4959)
IBM® Ethernet 10/100 Mbps (2968)  
10/100 Mbps Ethernet PCI Adapter II (4962)  
IBM 4-Port 10/100 Base-TX Ethernet PCI Adapter (4961) *  
10/100/1000 Base-T Ethernet PCI Adapter (2975)  
Gigabit Ethernet (2969)  
TURBOWAYS® 622 Mbps PCI MMF ATM Adapter (2946)  
2-Port Multiprotocol PCI Adapter (2962)  
8-Port and 128-Port 232/422 Async PCI Adapters (2943 and 2944)  
IBM 64-bit/66 MHz PCI ATM 155 adapter (4953 and 4957)

**Encryption Adapters:**  
IBM PCI 4758 Cryptographic Coprocessor Card (4958 and 4963) *  
IBM Crypto Accelerator (4960) *

**Graphics and Miscellaneous:**  
GXT135P Graphics Adapter (2848) *  
USB Open Host Controller (2737) *  
GXT4500P (2842)*  
GXT6500P (2843)*

**Note:** The devices above that are denoted with an asterisk (*) require the user to intervene and manually recover the device after a bus error is encountered (for example, through device reconfiguration). Also, you may need to reboot Graphics and USB devices because those devices may not completely recover. If the device encounters an error during the configuration process, the device will be left in the defined state until there is a subsequent configuration attempt.

**Known Problems**  
The following EEH error labels contain incorrect Description fields:  

<table>
<thead>
<tr>
<th>Label</th>
<th>Incorrect Description</th>
<th>Correct Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EEH_ERR</td>
<td>Unable to allocate in JFS2 snapshot</td>
<td>EEH Kernel services error</td>
</tr>
<tr>
<td>PCI_TEMP_ERR</td>
<td>Write error on JFS2 snapshot</td>
<td>EEH temporary error for adapter</td>
</tr>
<tr>
<td>PCI_PERM_ERR</td>
<td>Unable to write into a JFS2 snapshot</td>
<td>EEH permanent error for adapter</td>
</tr>
</tbody>
</table>

All other fields in the error log are correct and relevant to the EEH error. Error Ids contained in the `/usr/include/sys/errids.h` file are also correct. When contacting IBM service and support, please use the Error Id field. The following are the Error Ids for these labels:  

<table>
<thead>
<tr>
<th>Label</th>
<th>Error ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>EEH_ERR</td>
<td>A1E9B3BF</td>
</tr>
<tr>
<td>PCI_TEMP_ERR</td>
<td>07AFC8D7</td>
</tr>
<tr>
<td>PCI_PERM_ERR</td>
<td>D1E7854F</td>
</tr>
</tbody>
</table>

**Persistent Variables**  
DAs must store state variables in the `DAVars` Diagnostic Application Variables, object class to support loop mode. DAs are executed for each pass of loop mode, and thus lose state.

The `putdavar` and `getdavar` subroutines are used to put or get persistent variables.
Field Replaceable Units (FRUs)

DAs report FRU Buckets to identify parts that need to be replaced. The \texttt{addfrub} subroutine is used to add a FRU bucket to the \texttt{FRU Bucket} object class in the configuration database.

As part of the FRU information, a FRU part number for a fru not in the ODM database can be returned by the DA. The FRU part number is placed in the \texttt{DAVars} object class. Also, if the FRU bucket contains a sub-FRU (for example a memory module or daughter cards), the DA must return its physical or logical location code as part of the FRU bucket.

Each DA should base its good or bad status on the status of its children. A resource may pass its tests and be labeled bad when it has multiple children that have been labeled bad.

If a problem is detected with resource \(x\), which has a parent called resource \(y\) and a sibling called resource \(z\), then two FRU Buckets should be output.

- FRU Bucket 1 should identify the resources \(x\) and \(y\), and any cables that can be identified. If the cables cannot be uniquely identified, then the Service Repair Action should implicitly include any cables that may be needed.
- FRU Bucket 2 should only identify resource \(x\) and any cables if possible.

The Diagnostic Controller decides which FRU Bucket to use, based on the good/bad status of the sibling. If the sibling passes its tests, then FRU Bucket 2 is named.

Specifying a Text Conclusion

DAs can also specify a menu as a conclusion. A menu should be specified if the repair action can be performed by the customer. For example, if the problem can be solved by formatting a hard disk, then a menu should be specified.

The \texttt{menugoal} subroutine performs this function by adding the menu goal to the \texttt{Menugoal object class}.

Library Restrictions for Diagnostic Programs

Library \texttt{libc.a.min} is the libc included in the standalone diagnostic package. Do not use any function that is not part of \texttt{libc.a.min} in your application. If a function is used in a diagnostic program that is not an exported symbol of \texttt{libc.a.min}, then an immediate software error (803-xxx) occurs when attempting to run the diagnostic program in standalone diagnostic mode.

To ensure that all symbols used by your diagnostics application are included in the standalone environment, compile and link the application code with the \texttt{libc.a.min} library found in the \texttt{/usr/ccs/lib} directory.

One method is to create a directory containing the libraries needed for linking:

1. Copy libraries \texttt{libodm.a}, \texttt{libcfg.a}, and \texttt{libcrypt.a} to the new directory.
2. Make a link from \texttt{/usr/ccs/lib/libc.a.min} to \texttt{libc.a} in the new directory.
3. Make a link from \texttt{/usr/ccs/lib/libc.a.min} to \texttt{libbind.a} in the new directory.
4. Export \texttt{LIBPATH} to the new directory.
5. Compile and Link your application.

You can ignore any unresolved symbols coming from libasl, or others that you know about.

Errors found indicating unresolved symbols must be fixed before the program will properly execute in standalone diagnostics mode.
Guidelines for Writing Diagnostic Programs using C++

1. The standard library libC.a is not supported. Do not use this library’s API.
2. All of the language support functions in libC.a need to be statically linked at compile time. Use -lCns.a and -bI:/usr/lpp/xlC/lib/libC.imp arguments to compile with xlC.
3. Use an exception only for exceptional cases. For example, an exception should not be used for a program’s normal flow of control.
4. Never throw an exception across a shared library and executable boundaries.
5. No kernel extension shall be written in C++.

Completion Status for Diagnostic Applications

DAs must issue the macro DA_EXIT() to exit.

Individual values can be set by calling the appropriate DA_SETRC_XXXXXX() macro definition.

The following values are defined:

- DA_STATUS_GOOD: No problems were found.
- DA_STATUS_BAD: A FRU Bucket or a Menu Goal was reported.
- DA_USER_NOKEY: No special function keys were entered.
- DA_USER_EXIT: The Exit key was entered by the user.
- DA_USER.Quit: The Cancel key was entered by the user.
- DA_ERROR_NONE: No errors were encountered performing a normal operation such as displaying a menu, accessing the object repository, and allocating memory.
- DA_ERROR_OPEN: Could not open the device.
- DA_ERROR_OTHER: An error was encountered performing a normal operation.
- DA_TESTS_NOTEST: No tests were executed.
- DA_TEST_FULL: The full tests were executed.
- DA_TEST_SUB: The subtests were executed.
- DA_TEST_SHR: The shared tests were executed.
- DA_MORE_NOCONT: The isolation process is complete.
- DA_MORE_CONT: The path to the device should be tested. The next DA to be called is either the parent or sibling, depending on the value of DNext in the Predefined Diagnostic Resources PDiagRes object class.

Control Flow of a Diagnostic Application

The DA performs these tasks:

1. Displays first stand-by menu.
2. Obtains its input from the TMInput object class.
3. References the state1 and state2 variables in the TMInput object class to determine if the child devices which were tested during the current session are defective. If so, then the DA should name the parent as being bad.
4. Determines the level of tests to run.
5. Calls TU_OPEN.
6. Calls Application Test Units (TU).
7. Calls TU_CLOSE.
8. Reconfigures the device if DA caused it to be configured.
9. Performs error-log analysis if the dmode variable in the TMInput object class is equal to PD or ELA.
10. Returns status to the Diagnostic Controller through the DA_EXIT() macro call.
SRN Architecture

Diagnostic applications report problems through SRNs (Service Request Numbers). SRNs take the following forms:

- Six-digit SRNs consist of two grouping of three digits separated by the character "-" (for example, 922-101, where the first group of three digits is referred to as the source number. The second group of three digits is referred to as the reason code. The source number is a unique number that identifies the diagnostic application that produced the SRN. The source number is usually synonymous with the LED field of the PdDV object class of the configuration database. For a diagnostic application that cannot use the LED value, for whatever reason, a value must be assigned to avoid duplication. The reason code can be used to identify a particular failure cause detected by the diagnostic application.

- Other SRN Types. See the `addfrub` subroutine for details.

Six-digit SRNs should be grouped so that each set of FRU callouts are grouped together. For example, if a Diagnostic Application callout consists of:

- 10 SRNs for FRU A
- 20 SRNs for FRU B
- 5 SRNs for FRU A most likely with FRU B next
- 6 SRNs for FRU B most likely with FRU A next

Then the SRNs should be grouped like the following:

- 921-111 to 921-120 FRU A
- 921-131 to 921-150 FRU B
- 921-211 to 921-215 FRU A FRU B
- 921-221 to 921-226 FRU B FRU A

The guidelines for the Reason Codes for SRN Source Numbers 700 to 799 and 811 to 999 that are not decoded from some type of special information are:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>Reserved</td>
</tr>
<tr>
<td>001</td>
<td>Indicates that an adapter or device could not be found</td>
</tr>
<tr>
<td>002 to 100</td>
<td>Reserved</td>
</tr>
<tr>
<td>101 to 199</td>
<td>Reserved for non-ELA callouts with a single FRU</td>
</tr>
<tr>
<td>200 to 299</td>
<td>Reserved for non-ELA callouts with two FRUs</td>
</tr>
<tr>
<td>300 to 399</td>
<td>Reserved for non-ELA callouts with three FRUs</td>
</tr>
<tr>
<td>400 to 499</td>
<td>Reserved for non-ELA callouts with four or more FRUs</td>
</tr>
<tr>
<td>500 to 599</td>
<td>Reserved for non-ELA cases that require a special action such as waiting for a thermal device to cool or checking the level of a device.</td>
</tr>
<tr>
<td>600 to 699</td>
<td>Reserved for ELA callouts with a single FRU</td>
</tr>
<tr>
<td>700 to 799</td>
<td>Reserved for ELA callouts with two or more FRUs</td>
</tr>
<tr>
<td>800 to 899</td>
<td>Reserved for ELA cases that require a special action, such as waiting for a thermal device to cool or checking the level of a device.</td>
</tr>
<tr>
<td>900 to 999</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

This is done to group the SRNs with like FRUs into one entry in the SRN Tables.

Diagnostic Controller Generated SRNs

The following table lists SRN generated by the diagnostic controller when the event shown in the description column occurs.

**Note:** "xxx" in the following table represents the source number of the diagnostic application that executed.
<table>
<thead>
<tr>
<th>SRN</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>802-xxx</td>
<td>The diagnostic did not detect an installed device (Online Diagnostics).</td>
</tr>
<tr>
<td>803-xxx</td>
<td>An error not related to the diagnostic tests occurred.</td>
</tr>
<tr>
<td>804-xxx</td>
<td>A halt occurred in the diagnostic application.</td>
</tr>
<tr>
<td>801-101</td>
<td>The diagnostics did not detect an installed device (Standalone Diagnostics).</td>
</tr>
</tbody>
</table>

### Source Numbers

The following source numbers are defined for use by third party vendors.

**Note:** If the LED field of the PdDV object class for a particular device is different than the source number shown in the table below, the LED takes precedence. Source Numbers shown in the following table are hexadecimal values.

<table>
<thead>
<tr>
<th>Source Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>661</td>
<td>IDE Tape Drive</td>
</tr>
<tr>
<td>66a</td>
<td>USB Open Host Controller Type</td>
</tr>
<tr>
<td>66b</td>
<td>USB Universal Host Controller Type</td>
</tr>
<tr>
<td>74b</td>
<td>ATM Adapter</td>
</tr>
<tr>
<td>74d</td>
<td>Sound Card</td>
</tr>
<tr>
<td>74e</td>
<td>Fibre Channel Adapter</td>
</tr>
<tr>
<td>892</td>
<td>Graphics Display Adapter</td>
</tr>
<tr>
<td>893</td>
<td>Local Area Network (LAN) Adapter</td>
</tr>
<tr>
<td>894</td>
<td>Async Protocol Adapter</td>
</tr>
<tr>
<td>901</td>
<td>SCSI Protocol Device</td>
</tr>
<tr>
<td>902</td>
<td>Graphics Display</td>
</tr>
<tr>
<td>904</td>
<td>Parallel Port Attached Device</td>
</tr>
<tr>
<td>753</td>
<td>IDE CD ROM Drive</td>
</tr>
<tr>
<td>891</td>
<td>SCSI Device Adapter</td>
</tr>
<tr>
<td>752</td>
<td>IDE Disk Drive</td>
</tr>
<tr>
<td>805</td>
<td>CD Read/Write Drive</td>
</tr>
<tr>
<td>711</td>
<td>Generic Adapter (Not covered above)</td>
</tr>
</tbody>
</table>

### Diagnostic Application Code Checklist

The following checklist can be helpful in ensuring successful Diagnostic Application (DA) code.

1. Code must execute Good Machine Path (GMP) testing without abending or returning an SRN under the following conditions:
   a. IPL Mode: Service from hard disk.
   b. Select Advanced mode.
   c. Select PD mode.
   d. Run a single time.

   Follow all instructions presented by the DA. If the question presented on a screen is unclear, note the ambiguity and answer the question as you understand it.
Use wrap plugs where required. Unplug cables as required.

Look for:
   a. Spelling errors
   b. Grammatical errors

2. Code must execute GMP testing without abending or returning an SRN under the following conditions:
   a. IPL Mode: Service from CD-ROM.
   b. Select Advanced mode.
   c. Select PD mode.
   d. Run a single time.

Use wrap plugs where required. Unplug cables as required.

3. Code must execute GMP testing without abending or returning an SRN under the following conditions:
   a. IPL Mode: Normal.
   b. Run diagnostics from command line in no-console mode.
      ```
      diag -cd device
      ```
   c. Run diagnostics from command line in no-console Advanced mode.
      ```
      diag -Acdd device
      ```

4. Code must execute Good Machine Path (GMP) testing without abending or returning an SRN under
the following conditions:
   a. IPL Mode: Service from hard disk.
   b. Select PD mode.
   c. Select Advanced mode.
   d. Select ALL Resources.

Follow all instructions presented by the DA. If the question presented on a screen is unclear, note the
ambiguity and answer the question as you understand it.

Look for: No interactive menus displayed while the application is executing.

Other test scenarios include:

1. Bring the device to the DEFINED state; then run diagnostics to ensure the DA causes the device to be
made available. After testing is completed, ensure adapter is placed back in the DEFINED state.

2. If microcode is used by the device, rename the microcode file, run the DA, and make sure the DA
reports the absence of the file.

3. Run Advanced Diagnostics on the device. When a wrap plug is called for, do not use it. Make sure an
SRN is generated. Alternatively, do anything that causes an SRN to be reported. Check the SRN for
accuracy.

4. Try to cause an open error by renaming device driver. Ensure that a software error is reported.

5. Place the adapter in the DEFINED state. Cause the configuration to fail by renaming the method.
Observe how the DA handles this. In most instances, an SRN should be generated stating that the
device could not be configured.

6. Place the adapter in the second I/O planar of a supported system. Ensure the adapter is in the
DEFINIED state. Run diagnostics to ensure the DA causes the device to be made available. After
testing is completed, ensure adapter is placed back in the DEFINED state.

Tasks and Service Aids

The Diagnostic Package contains programs that are called Tasks. Tasks can be thought of as performing a
specific function on a resource; for example, running diagnostics, or performing a Service Aid on a
resource.
Creating a Task

Note: The diagnostic subsystem only supports 32-bit Tasks and Service Aids.

Tasks are represented by an entry in the [Predefined Diagnostic Task object class (PDiagTask)]. To create a new task, a PDiagTask object is needed plus the binary executable of the task itself, as specified by the PDiagTask->Action class member. When you are creating a task to display a subtask list, use a %name,comma separated list in the PDiagTask->Action field. The comma-separated list displays the TaskId values of each subtask TaskId. If a task and its subtasks have the same TaskId, a %name can be used. The following is an example of a task and subtask that have the same TaskId:

"%ThisTask,73,12,19" or "%ThisTask"

Some Task IDs are reserved for use by the Diagnostic Controller:

Task ID 0
   Built-in Controller Task

Task ID 1000+
   Reserved for Third-Party Use. Any number may be used above 999. A clash of task IDs by third-party tasks may occur if the same task ID is used. The problem may appear to the user as seeing a particular resource supported by a task, when in reality it is not. Each third-party supported task should be able to handle the condition of a nonsupported resource given as a command-line argument, if the PDiagTask->ResourceFlag is set.

Performing a Task

Menu
Select the following from the [Function Selection] Menu:

Task Selection (Diagnostics, Advanced Diagnostics, Service Aids, etc.)
This selection will list the tasks supported by these procedures.
Once a task is selected, a resource menu may be presented showing all resources supported by the task.

The displaying of the resource menu is dependent on the value of the PDiagTask->ResourceFlag value.

Note: Many of these tasks work on all system model architectures. (The [Diagnostic Task Matrix] shows all current supported tasks and their supported platforms.) Some tasks are only accessible from Online Diagnostics in Service or Concurrent mode, others may be accessible only from Standalone Diagnostics. While still other tasks may only be supported on a particular system architecture, such as CHRP (Common Hardware Reference Platform), or RSPC (PowerPC Reference Platform®).

Fastpath with Unknown Resource

A fastpath method is also available to perform a task by using the -T flag with the diag command. This means that the user does not have to go through most of the introductory menus just to get to a particular task. Instead the user is presented with a list of resources available that support the task specified.

The current fastpath tasks are:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>format</td>
<td>Format Media</td>
</tr>
<tr>
<td>certify</td>
<td>Certify Media</td>
</tr>
<tr>
<td>download</td>
<td>Download Microcode</td>
</tr>
<tr>
<td>umcode_latest</td>
<td>Download Latest Available Microcode</td>
</tr>
<tr>
<td>disp_mcode</td>
<td>Display Microcode Level</td>
</tr>
<tr>
<td>chkspares</td>
<td>Spare Sector Availability</td>
</tr>
<tr>
<td>identify</td>
<td>PCI RAID Physical Disk Identify</td>
</tr>
</tbody>
</table>
Fastpath with Known Resource
Each of these tasks can also be invoked directly from the command line specifying the resource and other task unique flags. This implies that the user already knows the resource to perform the task operation on. See publications Diagnostic Information for Micro Channel Bus Systems or Diagnostic Information for Multiple Bus Systems for more specific information on the tasks and flags.

Task List
The following is a list of all known supported tasks on the latest level of diagnostics. Tasks have been separated into one of six groups.

- Run Diagnostics
- Run Error Log Analysis
- Display or Change Diagnostic Run Time Options
- 7135 RAIDiant Array Service Aid
- Add or Delete Drawer Configuration
- Add Resource to Resource List
- AIX Shell Prompt
- Analyze Adapter Internal Log
- Backup and Restore Media
- Certify Media
- Change Hardware Vital Product Data
- Configure Dials and LPFKeys
- Configure ISA Adapter
- Configure Reboot Policy (CHRP)
- Configure Remote Maintenance Policy (CHRP)
- Configure Ring Indicate Power On Policy (CHRP)
- Configure Ring Indicate Power On (RSPC)
- Configure Service Processor (RSPC)
  - Call In/Out Setup
  - Modem Configuration
  - Site Specific Call In/Out Setup
  - Surveillance Setup
- Configure Surveillance Policy (CHRP)
- Create Customized Configuration Diskette
- Delete Resource from Resource List
- Disk Maintenance
  - Disk to Disk Copy
  - Display/Alter Sector
- Display Checkstop Analysis Results
- Display Configuration and Resource List
- Display Firmware Device Node Information (CHRP)
- Display Hardware Error Report
- Display Hardware Vital Product Data
- Display Machine Check Error Log
- Display Microcode Level
- Download Latest Available Microcode Level
- Display Previous Diagnostic Results
Add or Delete Drawer Configuration

Attention: This diagnostic task has been removed in AIX 5.2. The information has been retained for reference only.

Note: Not applicable to RSPC or CHRP systems.

This task invokes SMIT to provide the following options:

- List all Drawers
- Add a Drawer
- Remove a Drawer

The supported drawer types are:

- Media SCSI Device Drawer
• DASD SCSI DASD Drawer

Add Resource to Resource List
Use this task to add resources back to the resource list.

Note: Only resources that were previously detected by the diagnostics and deleted from the Diagnostic Test List are listed. If no resources are available to be added, then none are listed.

Shell Prompt

Note: Online Service Mode only.

This Service Aid allows access to the command line. To use this Service Aid the user must know the root password (when a root password has been established).

Do not use this task to install code, or change the configuration of the system. It is intended to be used to look at files, configuration, data, etc. Changing the system configuration, or installing code may produce problems after exiting back to the Diagnostic Controller.

Analyze Adapter Internal Log (Device Specific)
The PCI RAID adapter has an internal log that logs information about the adapter and the disk drives attached to the adapter. Whenever data is logged in the internal log, the device driver copies the entries to the system error log and clears the internal log.

The Analyze Adapter Internal Log Service Aid analyzes these entries in the system error log. The Service Aid displays the errors and the associated service actions. Entries that do not require any service actions are ignored.

Backup and Restore Media
This Service Aid allows verification of backup media and devices. It presents a menu of tape and diskette devices available for testing and prompts for selection of the desired device. It then presents a menu of available backup formats and prompts for selection of the desired format. The supported formats are tar, backup, and cpio. After the device and format are selected, the Service Aid backups a known file to the selected device, restores that file to /tmp, and compares the original file to the restored file. The restored file is also left in /tmp to allow for visual comparison. All errors are reported.

Certify Media
This task allows the selection of diskette or hardfiles to be certified. Hardfiles can be connected either to a SCSI adapter (non RAID) or a PCI SCSI RAID adapter. The usage and certify criteria for a hardfile connected to a non RAID SCSI adapter are different from those for a hardfile connected to a PCI SCSI RAID adapter.

Note: The certify function for devices attached to a PCI SCSI RAID adapter is supported for certain PCI SCSI RAID adapters only.

This task may be run directly from the command line. The following usage statement describes the syntax of the fastpath command:

Usage:
diag -T "certify"
Change Hardware Vital Product Data
Use this Service Aid to display the Display/Alter VPD Selection Menu. The menu lists all resources installed on the system. When a resource is selected, a menu displays all the VPD that are recognized by the operating system for that resource.

Note: The user cannot alter the VPD for a specific resource unless it is not machine readable.

Configure Dials and LPFKeys
This Service Aid provides a tool for configuring and removing dials/LPFKs to the asynchronous serial ports.

Since version 4.1.3 a tty must be defined on the async port before the Dials and LPFKs can be configured on the port. Before version 4.2 the Dials and LPFKs could only be configured on the standard serial ports. At version 4.2 the Dials and LPFKs can be configured on any async port.

This selection invokes the SMIT utility to allow Dials and LPFKs configuration. A tty must be in the available state on the async port before the Dials and LPFKs can be configured on the port. The task allows an async adapter to be configured, then a tty port defined on the adapter, and then Dials and LPFKs can be defined on the port.

Configure ISA Adapter

Attention: This diagnostic task has been removed in AIX 5.2. The information has been retained for reference only.

This task invokes SMIT to allow the identification and configuration of ISA adapters on systems that have an ISA bus and adapters.

Diagnostic support for ISA adapters not shown in the list may be supported from a Supplemental Diskette. ISA adapter support can be added from a Supplemental Diskette with the Process Supplemental Media task.

Whenever an ISA adapter is installed, this Service Aid must be run and the adapter configured before the adapter can be tested. This Service Aid must also be run (and the adapter removed) whenever an ISA adapter is physically removed from the system.

If diagnostics are run on an ISA adapter that has been removed from the system, the diagnostics fail.

ISA adapters cannot be detected by the system.

Note: When using this Service Aid choose the option that places the adapter in the “Defined State”. Do not select the option that places the device in the “Available State”.

Configure Reboot Policy (CHRP) on POWER4 and earlier RS/6000 systems
This Service Aid controls how the system tries to recover from a system crash.

Use this Service Aid to display and change the following settings for the Reboot Policy.

Notes:
1. This Service Aid runs on POWER4™ and earlier RS/6000® CHRP systems units only.
2. Because of system capability, some of the following settings may not be displayed by this Service Aid.
   • Maximum Number of Reboot Attempts
Enter a number that is 0 or greater.

**Note:** A value of 0 indicates ‘do not attempt to reboot’ to a crashed system.

This number is the maximum number of consecutive attempts to reboot the system. The term "reboot", in the context of this Service Aid, is used to describe bringing system hardware back up from scratch, for example from a system reset or power on.

When the reboot process completes successfully, the reboot attempts count is reset to 0, and a “restart” begins. The term “restart”, in the context of this Service Aid, is used to describe the operating system activation process. Restart always follows a successful reboot.

When a restart fails, and a restart policy is enabled, the system attempts to reboot for the maximum number of attempts.

**• Use the O/S Defined Restart Policy (1=Yes, 0=No)**

When ‘Use the O/S Defined Restart Policy’ is set to Yes, the system attempts to reboot from a crash if the operating system has an enabled Defined Restart or Reboot Policy.

When ‘Use the O/S Defined Restart Policy’ is set to No, or the operating system restart policy is undefined, then the restart policy is determined by the ‘Supplemental Restart Policy’.

**• Enable Supplemental Restart Policy (1=Yes, 0=No)**

The ‘Supplemental Restart Policy’, if enabled, is used when the O/S Defined Restart Policy is undefined, or is set to False.

When surveillance detects operating system inactivity during restart, an enabled ‘Supplemental Restart Policy’ causes a system reset and the reboot process begins.

**• Call-Out Before Restart (on/off)**

When enabled, Call-Out Before Restart allows the system to call out (on a serial port that is enabled for call out) when an operating system restart is initiated. Such calls can be valuable if the number of these events becomes excessive, thus signaling bigger problems.

**• Enable Unattended Start Mode (1=Yes, 0=No)**

When enabled, ‘Unattended Start Mode’ allows the system to recover from the loss of AC power.

If the system was powered-on when the AC loss occurred, the system reboots when power is restored. If the system was powered-off when the AC loss occurred, the system remains off when power is restored.

This Service Aid may be accessed directly from the command line, by entering:

```
/usr/lpp/diagnostics/bin/uspchrp -b
```

**Configure Reboot Policy (CHRP) on POWER5 Systems or Later**

This Service Aid controls how the system tries to recover when power is restored after a power outage.

Use this Service Aid to display and change the following setting for the Reboot Policy.

**Notes:**

1. This Service Aid runs only on POWER5™ systems or later.

**• Enable Platform Automatic Power Restart**

When enabled, Enable Platform Auto Power Restart allows the platform firmware to restart a system after power is restored following a power outage. If the system is partitioned, each partition that was running when the power outage occurred is restarted as indicated by that partition’s setting of the SMIT option:

```
Automatically REBOOT operating system after a crash
```

This Service Aid can be accessed directly from the command line by typing:

```
/usr/lpp/diagnostics/bin/uspcchrp -b
```
The parameter setting can be read and set directly from the command line. To read the parameter, run the following command:

```
/usr/lpp/diagnostics/bin/uspchrp -q platform-auto-power-restart
```

To set the parameter, run the following command:

```
/usr/lpp/diagnostics/bin/uspchrp -e platform-auto-power-restart=[0|1]
```

where

- 1 = Enable Platform Automatic Power Restart
- 0 = Disable Platform Automatic Power Restart

**Configure Remote Maintenance Policy (CHRP)**

The Remote Maintenance Policy includes modem configurations and phone numbers to use for remote maintenance support.

Use this Service Aid to display and change the following settings for the Remote Maintenance Policy.

**Notes:**

1. Runs on CHRP systems units only.
2. Because of system capability, some of the following settings may not be displayed by this Service Aid.

- **Configuration File for Modem on S1**
  - **Configuration File for Modem on S2**
  Enter the name of a modem configuration file to load on either serial port 1 (S1) or serial port 2 (S2). The modem configuration files are located in the directory `/usr/share/modems`. If a modem file is already loaded, it is showed by `Modem file currently loaded`.

- **Modem file currently loaded on S1**
  - **Modem file currently loaded on S2**
  This is the name of the file that is currently loaded on serial port 1 or serial port 2.

**Note:** These settings are only shown when a modem file is loaded for a serial port.

- **Call In Authorized on S1 (on/off)**
  - **Call In Authorized on S2 (on/off)**
  Call In allows the Service Processor to receive a call from a remote terminal.

- **Call Out Authorized on S1 (on/off)**
  - **Call Out Authorized on S2 (on/off)**
  Call Out allows the Service Processor to place calls for maintenance.

- **S1 Line Speed**
  - **S2 Line Speed**
  A list of line speeds is available by using 'List' on the screen.

- **Service Center Phone Number**
  This is the number of the service center computer. The service center usually includes a computer that takes calls from systems with call-out capability. This computer is referred to as "the catcher". The catcher expects messages in a specific format to which the Service Processor conforms. For more information about the format and catcher computers, refer to the README file in the `/usr/samples/syscatch` directory. Contact the service provider for the correct telephone number to enter here.

- **Customer Administration Center Phone Number**
  This is the number of the System Administration Center computer (catcher) that receives problem calls from systems. Contact the system administrator for the correct telephone number to enter here.

- **Digital Pager Phone Number In Event of Emergency**
  This is the number for a pager carried by someone who responds to problem calls from your system.
• **Customer Voice Phone Number**  
  This is the number for a telephone near the system, or answered by someone responsible for the system. This is the telephone number left on the pager for callback.

• **Customer System Phone Number**  
  This is the number to which your system’s modem is connected. The service or administration center representatives need this number to make direct contact with your system for problem investigation. This is also referred to as the Call In phone number.

• **Customer Account Number**  
  This number could be used by a service provider for record keeping and billing.

• **Call Out Policy Numbers to call if failure**  
  This is set to either 'first' or 'all'. If the call out policy is set to 'first', call out stops at the first successful call to one of the following numbers in the order listed:
  1. Service Center
  2. Customer Admin Center
  3. Pager
  If Call Out Policy is set to 'all', call out attempts to call all of the following numbers in the order listed:
  1. Service Center
  2. Customer Admin Center
  3. Pager

• **Customer RETAIN Login ID**  
  **Customer RETAIN Login Password**  
  These settings apply to the RETAIN® service function.

• **Remote Timeout, in seconds**  
  **Remote Latency, in seconds**  
  These settings are functions of the service provider’s catcher computer.

• **Number of Retries While Busy**  
  This is the number of times the system should retry calls that resulted in busy signals.

• **System Name (System Administrator Aid)**  
  This is the name given to the system and is used when reporting problem messages.

  **Note:** Knowing the system name aids the support team to quickly identify the location, configuration, history, etc. of your system.

This Service Aid may be accessed directly from the command line, by entering:  
/usr/lpp/diagnostics/bin/uspcrhp -m

### Configure Ring Indicate Power On (RSPC)

**Attention:** This diagnostic task has been removed in AIX 5.2. The information has been retained for reference only.

This Service Aid allows the user to display and change the NVRAM settings for the Ring Indicate Power On capability of the service processor.

**Note:** Runs on RSPC systems units only.

The settings allows the user to:
• Enable/Disable power on from Ring Indicate
• Read/Set the number of rings before power on
Configure Ring Indicate Power On Policy (CHRP)

This Service Aid allows the user to power on a system by telephone from a remote location. If the system is powered off, and Ring Indicate Power On is enabled, the system powers on at a predetermined number of rings. If the system is already on, no action is taken. In either case, the telephone call is not answered and the caller receives no feedback that the system has powered on.

Use this Service Aid to display and change the following settings for the Ring Indicate Power On Policy.

Notes:
1. Runs on CHRP systems units only.
2. Because of system capability, some of the following settings may not be displayed by this Service Aid.
   • Power On Via Ring Indicate (on/off)
   • Number of Rings Before Power On

This Service Aid may be accessed directly from the command line, by entering:
/usr/lpp/diagnostics/bin/usphrp -r

Configure Service Processor (RSPC)

Attention: This diagnostic task has been removed in AIX 5.2. The information has been retained for reference only.

This Service Aid allows you to display and change the NVRAM settings for the service processor.

This Service Aid supports the following functions:

Note: Runs on RSPC systems units only.
• Surveillance Setup
• Modem Configuration
• Call In/Call Out Setup
• Site Specific Call In/Call Out Setup

Surveillance Setup

This selection allows you to display and change the NVRAM settings for the surveillance capability of the service processor.

The settings allow you to:
• Enable/disable surveillance
• Set the surveillance time interval, in minutes
• Set the surveillance delay, in minutes

The current settings are read from NVRAM and displayed on the screen. Any changes made to the data shown are written to NVRAM.

Modem Configuration

Use this selection when setting the NVRAM for a modem attached to any of the Service Processor’s serial ports. The user inputs the file name of a modem configuration file and the serial port number. The formatted modem configuration file is read, converted for NVRAM than loaded into NVRAM. Refer to the Service Processor Installation and User’s Guide for more information.
Call In/Out Setup
This selection allows the user to display and change the NVRAM settings for the Call In/Call Out capability of the service processor.

The settings allows the user to:
- Enable/Disable call in on either serial port.
- Enable/Disable call out on either serial port.
- Set the line speed on either serial port.

Site Specific Call In/Out Setup
This selection allows you to display and change the NVRAM settings that are site specific for the call in/call out capability of the service processor.

The site specific NVRAM settings allow you to:
- Set the phone number for the service center
- Set the phone number for the customer administration center
- Set the phone number for a digital pager
- Set the phone number for the customer system to call in
- Set the phone number for the customer voice phone
- Set the customer account number
- Set the call out policy
- Set the customer RETAIN ID
- Set the customer RETAIN password
- Set the remote timeout value
- Set the remote latency value
- Set the number of retries while busy
- Set the system name

The current settings are read from NVRAM and displayed on the screen. Any changes made to the data shown are written to NVRAM.

Configure Surveillance Policy (CHRP)
This Service Aid monitors the system for hang conditions, that is, hardware or software failures that cause operating system inactivity. When enabled, and surveillance detects operating system inactivity, a call is placed to report the failure.

Use this Service Aid to display and change the following settings for the Surveillance Policy.

Notes:
1. Runs on CHRP systems units only.
2. Because of system capability, some of the following settings may not be displayed by this Service Aid.
   - Surveillance (on/off)
   - Surveillance Time Interval
     This is the maximum time between heartbeats from the operating system.
   - Surveillance Time Delay
     This is the time to delay between when the operating system is in control and when to begin operating system surveillance.
   - Changes are to take affect immediately
Set this to Yes if the changes made to the settings in this menu are to take place immediately. Otherwise the changes takes place beginning with the next system boot.

This Service Aid may be accessed directly from the command line, by entering:

```
/usr/lpp/diagnostics/bin/uspchrp -s
```

**Create Customized Configuration Diskette**

This selection invokes the Diagnostic Package Utility Service Aid which allows the user to Create a Standalone Diagnostic Package Configuration Diskette

The Standalone Diagnostic Package Configuration Diskette allows the following to be changed when running diagnostics from removable media:

- **High-Function Terminals 60/77-Mhz Refresh Rate**
  The refresh rate used by the standalone diagnostic package is 60Hz. If the display’s refresh rate is 77Hz, then set the refresh rate to 77.

- **Different async terminal console**
  A console configuration file that allows a terminal attached to any RS232 or RS422 adapter to be selected as a console device can be created using this Service Aid. The default device is a RS232 tty attached to the first standard serial port (S1).

**Delete Resource from Resource List**

Use this task to delete resources from the resource list.

**Note:** Only resources that were previously detected by the diagnostics and have not been deleted from the Diagnostic Test List are listed. If no resources are available to be deleted, then none are listed.

**Disk Maintenance (SCSI Disks)**

- Disk to Disk Copy
- Display/Alter Sector

**Disk to Disk Copy**

This selection allows you to recover data from an old drive when replacing it with a new drive. The Service Aid only supports copying from a drive to another drive of similar size. This Service Aid cannot be used to update to a different size drive. The `migratepv` command should be used when updating drives. The Service Aid recovers all LVM software reassigned blocks. To prevent corrupted data from being copied to the new drive, the Service Aid aborts if an unrecoverable read error is detected. To help prevent possible problems with the new drive, the Service Aid aborts if the number of bad blocks being reassigned reaches a threshold.

**Note:** Use the `migratepv` command when copying the contents to other disk drive types. This command also works when copying SCSI disk drives or when copying to a different size SCSI disk drive. Refer to *Operating system and device management* for a procedure on migrating the contents of a physical volume.

The procedure for using this Service Aid requires that both the old and new disks be installed in or attached to the system with unique SCSI addresses. This requires that the new disk drive SCSI address must be set to an address that is not currently in use and the drive be installed in an empty location. If there are no empty locations, then one of the other drives must be removed. Once the copy is complete, only one drive may remain installed. Either remove the target drive to return to the original configuration, or perform the following procedure to complete the replacement of the old drive with the new drive.

1. Remove both drives.
2. Set the SCSI address of the new drive to the SCSI address of the old drive.
3. Install the new drive in the old drive’s location.
4. Install any other drives that were removed into their original location.

To prevent problems that may occur when running this Service Aid from disk, it is suggested that this Service Aid be run from the diagnostics that are loaded from removable media when possible.

**Display/Alter Sector**

This selection allows the user to display and alter information on a disk sector. Care must be used when using this Service Aid because inappropriate modification to some disk sectors may result in total loss of all data on the disk. Sectors are addressed by their decimal sector number. Data is displayed both in hex and in ASCII. To prevent corrupted data from being incorrectly corrected, the Service Aid does not display information that cannot be read correctly.

**Display Checkstop Analysis Results**

**Attention:** This diagnostic task has been removed in AIX 5.2. The information has been retained for reference only.

This Service Aid analyzes checkstop files and displays the results. During a system reboot, following a checkstop, a data file is written to /usr/lib/ras that contains the state of the system at the time of the checkstop. The files have names that begin with `checkstop` and end with either `.A` or `.B`.

The analysis of the file(s) produce a description of the problem and provide an action plan with repair instructions or recommendations. Following the action plans, a detailed dump of the data that was saved for the checkstop is displayed.

The following options are provided:

- **Analyze Checkstop Files Created Within the Last 7 Days**
  
  Analyze and display the results of any checkstop file that was created in the last 7 days. This is the same file(s) that the system planar diagnostics analyzed, but will provide more detail.

- **Analyze All of the Checkstop Files**
  
  Analyze and display the results of all of checkstop files.

For either option, carefully read the results of the analysis and perform any recommended actions.

**Display Configuration and Resource List**

This Service Aid displays the item header only for all installed resources. Use this Service Aid when there is no need of seeing the VPD. (No VPD is displayed.)

**Display Firmware Device Node Information (CHRP)**

This task displays the firmware device node information that appears on CHRP platforms. The format of the output data does not necessarily have to be the same between different levels of the operating system. It is intended to be used to gather more information about individual or particular devices on the system.

**Note:** Runs on CHRP systems units only.

**Display Hardware Error Report**

This Service Aid provides a tool for viewing the hardware error log. It uses the `errpt` command.

The Display Error Summary and Display Error Detail selection provide the same type of report as the `errpt` command. The Display Error Analysis Summary and Display Error Analysis Detail selection provide additional analysis.
Display Hardware Vital Product Data
This Service Aid displays all installed resources along with any VPD that is recognized by the operating system for those resources. Use this Service Aid when you want to look at the VPD for a specific resource.

Display Machine Check Error Log
When a machine check occurs, information is collected and logged in a NVRAM error log before the system unit shuts down. This information is logged in the error log and cleared from NVRAM when the system is rebooted from either hard disk or LAN. The information is not cleared when booting from Standalone Diagnostics, this Service Aid can take the logged information and turn it into a readable format that can be used to isolate the problem. When booting from the hard disk or LAN, the information can be viewed from the error log using the Hardware Error Report Service Aid. In either case the information is analyzed when running the sysplanar0 diagnostics in Problem Determination Mode.

*Note:* The Machine Check Error Log Service Aid is available only on Standalone Diagnostics.

Display Microcode Level
This selection, located in the Microcode Tasks submenu, provides a way to display microcode on a device or adapter. Once invoked, a list of resources are available for selection that supports this function. Once a resource is selected, a specific application that supports that function on the resource is invoked. See the description on [PDiagAtt](#) for the stanza that is needed to achieve this.

This task may be run directly from the command line. The following usage statement describes the syntax of the fastpath command:

**Usage:**

diag -T "disp_mcode"

Display or Change Bootlist
This Service Aid allows the bootlist to be displayed, altered, or erased.

The system attempts to perform an IPL from the first device in the list. If the device is not a valid IPL device or if the IPL fails, the system proceeds in turn to the other devices in the list to attempt an IPL.

Display or Change BUMP Configuration

*Attention:* This diagnostic task has been removed in AIX 5.2. The information has been retained for reference only.

This Service Aid is unique to the POWER-based SMP system units and provides the following functions:

- **Display or Change Remote Support Phone Number**
  This function allows the remote support phone number to be displayed or altered.

- **Display or Change Diagnostics Modes**
  This function displays a dialog screen that lists the states of all the BUMP (Bringup Micro-Processor) Diagnostic Flags. The states can be changed via the dialog screen.

- **Save or Restore Diagnostics Modes and Remote Support Phone Number**
  This function allows the diagnostics modes and remote support phone number to be saved or restored. The location of the save area is to be defined.

- **Flash EPROM Download**
  This function updates the Flash EPROM.
**Display or Change Diagnostic Run Time Options**

The Display or Change Diagnostic Run Time Options task allows the diagnostic run time options to be set.

The run time options are:

- **Display Diagnostic Mode Selection Menus**
  This option allows the user to turn on or turn off displaying the DIAGNOSTIC MODE SELECTION MENU. The default value is on.

- **Include Advanced Diagnostics**
  This option allows the user to turn on or off including the Advanced Diagnostics. The default value is off.

- **Run Tests Multiple Times**
  This option allows the user to turn on or off running the diagnostic in Loop Mode. The default value is off.

  **Note:** This option is only displayed when running Online Diagnostics in Service Mode.

- **Include Error Log Analysis**
  This option allows the user to turn on or off including the Error Log Analysis (ELA). The default value is off.

- **Number of days used to search error log**
  This option allows the user to select the number of days to search the error log for errors when running Error Log Analysis. The default value is 7 days, but can be changed from 1 to 60 days.

- **Display Progress Indicators**
  This option allows the user to turn on or off the progress indicators shown when running Diagnostic Applications. The progress indicators are a popup box at the bottom of the screen indicating the test being run. The default value is on.

- **Diagnostic Event Logging**
  This option allows the user to turn on or off logging information to the Diagnostics Event Log. The default value is on.

- **Diagnostic Event Log file size**
  This option allows the user to select the maximum size of the Diagnostic Event Log. The default value is 100K, but can be changed from 100K to 1000K.

- **Save changes to the database**
  This option allows the user to save any changes made to the run time options. Without saving the changes, any changes made are only applicable to that session of diagnostics. The default value is no.

**Display or Change Electronic Mode Switch**

**Attention:** This diagnostic task has been removed in AIX 5.2. The information has been retained for reference only.

This Service Aid is unique to the POWER-based SMP system units and displays the states of the Physical and Electronic Keys. It also allows the electronic keys to be set.

**Display or Change Multiprocessor Configuration (Multiprocessor Service)**

**Attention:** This diagnostic task has been removed in AIX 5.2. The information has been retained for reference only.

This Service Aid is unique to the POWER-based SMP system units and provides the following functions:
• **Display or Change Processor States**
  This function displays or changes the state of available processors.

• **Bind Process**
  This function provides a tool for binding a process and all its threads to a specified processor.

**Display Previous Diagnostic Results**

This service aid allows a service representative to display results from a previous diagnostic session. When the **Display Previous Results** option is selected, the user will be able to view up to 25 no trouble found (NTF) and service request number (SRN) results.

This service aid also displays diagnostic log information. The diagnostic log can be displayed in a short version or a long version. The diagnostic log contains information about events logged by a diagnostic session.

This service aid displays the information in reverse chronological order. If more information is available than what can be displayed on the screen, the Page Down and Page Up keys can be used to scroll through the information.

**Note:** This Service Aid is not available when you load the diagnostics from a source other than a disk drive or from a network.

This information is not from the error log maintained by the operating system. This information is stored in the `/var/adm/ras` directory.

**Display Resource Attributes**

This task displays the Customized Device Attributes associated with a selected resource. This task is similar to running the `lsattr -E -l resource` command.

**Display Service Hints**

This Service Aid reads and displays the information in the `CEReadme` file from the diagnostics media. This file contains information that is not in the publications for this version of the diagnostics. It also contains information about using this particular version of diagnostics.

This Service Aid presents a menu if multiple `CEReadme` files are present in the `/usr/lpp/diagnostics/` directory. This allows other non-related `CEReadme` files to be displayed containing information about unrelated functions.

Use the arrow keys to scroll through the information in the file.

**Display Software Product Data**

This task invokes SMIT to display information about the installed software and provides the following functions:

• List Installed Software
• List Applied but Not Committed Software Updates
• Show Software Installation History
• Show Fix (APAR) Installation Status
• List Fileset Requisites
• List Fileset Dependents
• List Files Included in a Fileset
• List File Owner by Fileset
Display System Environmental Sensors (CHRP)

This Service Aid displays the environmental sensors implemented on a CHRP system. The information displayed is the sensor name, physical location code, literal value of the sensor status, and the literal value of the sensor reading.

**Note:** Runs on CHRP systems units only.

The sensor status can be any one of the following:

- **Normal**
  The sensor reading is within the normal operating range.

- **Critical High**
  The sensor reading indicates a serious problem with the device. Run diagnostics on sysplanar0 to determine what repair action is needed.

- **Critical Low**
  The sensor reading indicates a serious problem with the device. Run diagnostics on sysplanar0 to determine what repair action is needed.

- **Warning High**
  The sensor reading indicates a problem with the device. This could become a critical problem if action is not taken. Run diagnostics on sysplanar0 to determine what repair action is needed.

- **Warning Low**
  The sensor reading indicates a problem with the device. This could become a critical problem if action is not taken. Run diagnostics on sysplanar0 to determine what repair action is needed.

- **Hardware Error**
  The sensor could not be read because of a hardware error. Run diagnostics on sysplanar0 in problem determination mode to determine what repair action is needed.

- **Hardware Busy**
  The system has repeatedly returned a busy indication, and a reading is not available. Try the Service Aid again. If the problem continues, run diagnostics, on sysplanar0 in problem determination mode to determine what repair action is needed.

This Service Aid can also be run as a command. The command can be used to list the sensors and their values in a text format, list the sensors and their values in numerical format, or a specific sensor can be queried to return either the sensor status or sensor value.

The command can be run by entering one of the following:

```
/usr/lpp/diagnostics/bin/uesensor -l | -a
/usr/lpp/diagnostics/bin/uesensor -t token -i index [-v]
```

**Flags**

- `-l` List the sensors and their values in a text format.
- `-a` List the sensors and their values in a numerical format. For each sensor, the following numerical values are displayed as:
  `<token> <index> <status> <measured value> <location code>`
- `-t token` Specifies the sensor token to query.
- `-i index` Specifies the sensor index to query.
- `-v` Indicates to return the sensor measured value. The sensor status is returned by default.
Examples

1. Display a list of the environmental sensors:
   `/usr/lpp/diagnostics/bin/uesensor -l`
   
   Sensor Token = Fan Speed
   Status = Normal
   Value = 2436 RPM
   Location Code = F1
   
   Sensor Token = Power Supply
   Status = Normal
   Value = Present and operational
   Location Code = V1
   
   Sensor Token = Power Supply
   Status = Critical low
   Value = Present and not operational
   Location Code = V2

2. Display a list of the environmental sensors in a numerical list:
   `/usr/lpp/diagnostics/bin/uesensor -a`
   
   3 0 11 87 P1
   9001 0 11 2345 F1
   9004 0 11 2 V1
   9004 1 9 2 V2

3. Return the status of sensor 9004, index 1:
   `/usr/lpp/diagnostics/bin/uesensor -t 9004 -i 1`
   
   9

4. Return the value of sensor 9004, index 1:
   `/usr/lpp/diagnostics/bin/uesensor -t 9004 -i 1 -v`
   
   2

Display Test Patterns

This Service Aid provides a means of adjusting system display units by providing displayable test patterns. Through a series of menus the user selects the display type and test pattern. After the selections are made, the test pattern is displayed.

Download Microcode

This selection, located in the Microcode Tasks submenu, provides a way to update microcode to a device or adapter. Once invoked, a list of resources are available for selection that supports this function. Once a resource is selected, a specific application that supports that function on the resource is invoked. See the description on [PDiagAtt](#) for the stanza that is needed to achieve this.

This task may be run directly from the command line. The following usage statement describes the syntax of the fastpath command:

Usage:
```
diag -T "download"
```

Download Latest Available Microcode

This selection, located in the Microcode Tasks submenu, provides a way to determine which resources can be updated from a specified source of microcode images. After you select a source of microcode images from a list of possible sources, a list of resources is displayed, where each resource in the list was found to have an older firmware image than what is available on the specified source. From this list, you can select any or all of the resources. Then the resource specific download task is executed to update the microcode with the image on the specified source.
This task may be entered directly from the command line. The following usage statement describes the syntax of the fastpath command:

Usage:
diag -T "download_latest [-s source]"

The command form of this task is:
/usr/lpp/diagnostics/bin/umcode_latest

For more information, refer to the umcode_latest command.

ESCON Bit Error Rate

Attention: This diagnostic task has been removed in AIX 5.2. The information has been retained for reference only.

This Service Aid is used to check the bit error rate for an ESCON® adapter to assure that the link to the host system is functioning properly. To run the ESCON Bit Error Rate Service Aid, the adapter must be connected, configured, and on-line. If the adapter is not configured properly, the Service Aid is not able to check the bit error rate.

Fibre Channel RAID (Device Specific)

The Fibre Channel RAID Service Aids contain the following functions:

- **Certify LUN**
  This selection reads and checks each block of data in the LUN. If excessive errors are encountered the user is notified.
  This task may be run directly from the command line. The following usage statement describes the syntax of the fastpath command:
  Usage:
  ```
  diag -T "certify"
  ```

- **Certify Spare Physical Disk**
  This selection allows the user to certify (check the integrity of the data) on drives designated as spares.
  This task may be run directly from the command line. The following usage statement describes the syntax of the fastpath command:
  Usage:
  ```
  diag -T "certify"
  ```

- **Format Physical Disk**
  This selection is used to format a selected disk drive.
  This task may be run directly from the command line. The following usage statement describes the syntax of the fastpath command:
  Usage:
  ```
  diag -T "format"
  ```

- **Array Controller Microcode Download**
  This selection allows the microcode on the Fibre Channel RAID controller to be updated when required.
  This task may be run directly from the command line. The following usage statement describes the syntax of the fastpath command:
  Usage:
  ```
  diag -T "download"
  ```

- **Physical Disk Microcode Download**
  This selection is used to update the microcode on any of the disk drives in the array.
This task may be run directly from the command line. The following usage statement describes the syntax of the fastpath command:

Usage:

diag -T "download"

- **Update EEPROM**
  This selection is used to update the contents of the EEPROM on a selected controller.

- **Replace Controller**
  Use this selection when it is necessary to replace a controller in the array.

**Flash SK-NET FDDI Firmware**
This task allows the Flash firmware on the SysKonnect SK-NET FDDI adapter to be updated.

**Format Media**
The Format Media task supports the selection of diskettes, SCSI hardfiles, or SCSI optical media.

This task may be run directly from the command line. The following usage statement describes the syntax of the fastpath command:

Usage:

diag -T "format"

**Generic Microcode Download**
This Service Aid, located in the Microcode Tasks submenu, provides a means of executing a “generic” script from a diskette. The intended purpose for this “generic” script is to load microcode to a supported resource. This script is responsible for executing whatever program is required in order to download the microcode onto the adapter or device.

This Service Aid is supported in both concurrent and standalone modes from disk, LAN, or removable media.

On entry, the Service Aid displays information about what it does. It then asks for a “Genucode” diskette to be inserted into the diskette drive. The diskette must be in tar format. The Service Aid then restores the script file, “genucode”, to the /tmp directory. Then the script is executed. The script must at that point then pull off any other needed files from the diskette. The script should then exec whatever program is necessary in order to perform its function. On completion, a status code is returned, and the user is returned to the Service Aid.

The genucode script should have a #!/usr/bin/ksh line at the beginning of the file. Return status of 0 should be returned if the program was successful, else a non-zero status should be returned.

**Hot Plug Task**
This Service Aid allows the user to choose a SCSI device or location from a menu and to identify a device, located in a 7027 system unit.

The Service Aid also does the following:
- Generates a menu displaying all SCSI devices.
- Lists the device and all of its sibling devices.
- List all SCSI adapters and their ports.
- List all SCSI devices on a port.
Local Area Network Analyzer
This selection is used to exercise the LAN communications adapters (Token-Ring, Ethernet, and (FDDI) Fiber Distributed Data Interface). The following services are available:

- **Connectivity testing between two network stations**
  Data is transferred between the two stations. This requires the user to input the Internet Addresses of both stations.

- **Monitoring ring (Token-Ring only)**
  The ring is monitored for a period of time. Soft and hard errors are analyzed.

Log Repair Action
The Log Repair Action task logs a repair action in the AIX Error Log. A Repair Action log indicates that an FRU has been replaced, and error log analysis should not be done for any errors logged before the repair action. The Log Repair Action task lists all resources. Replaced resources can be selected from the list, and when commit (F7 key) is selected, a repair action is logged for each selected resource.

The Log Repair Action can also be logged from the command line, using the `diag` command. The syntax is the following:

```
diag -c -d Resource -L pending | complete
```

where

- **pending** indicates the part has been replaced, but it is not yet known if this part will remain in the system.
- **complete** indicates the part has been replaced and it is known that this part will remain in the system.

Microcode Tasks
This selection provides a way to access the microcode and flashing features of Display Microcode Level, Download Microcode, Generic Microcode Download, and Update and Manage System Flash/Update System or Service Processor Flash.

Display MultiPath I/O (MPIO) Device Configuration
The Display MultiPath I/O (MPIO) Device Configuration service aid displays the status of MPIO devices and their connections to their parents. It is capable of sending SCSI commands on each available path regardless of the default MPIO path algorithm, therefore, it is useful for testing the unused path for integrity. You may wish to run this service aid if you suspect there is a problem with the path between MPIO devices and their parents.

This service aid is capable of the following:

1. Listing MPIO devices
2. Listing the parents of MPIO devices
3. Displaying the status and location of specified MPIO devices.
4. Displaying the hierarchy of MPIO adapters and devices

You can access this service aid directly from the AIX command line, by typing:

```
/usr/lpp/diagnostics/bin/umpio
```

**Flags:** None.

PCI RAID Physical Disk Identify
This selection identifies physical disks connected to a PCI SCSI-2 F/W RAID adapter.
This task may be run directly from the command line. The following usage statement describes the syntax of the fastpath command:

Usage:
```bash
diag -T "identify"
```

**Periodic Diagnostics**

This selection provides a tool for configuring periodic diagnostics and automatic error log analysis. A hardware resource can be chosen to be tested once a day, at a user specified time. If the resource cannot be tested because it is busy, error log analysis is performed. Hardware errors logged against a resource can also be monitored by enabling Automatic Error Log Analysis. This allows error log analysis to be performed every time a hardware error is put into the error log. If a problem is detected, a message is posted to the system console and a mail message sent to the user(s) belonging to the system group with information about the failure such as Service Request Number.

The Service Aid provides the following functions:
- Add or delete a resource to the periodic test list
- Modify the time to test a resource
- Display the periodic test list
- Modify the error notification mailing list
- Disable or Enable Automatic Error Log Analysis

**Process Supplemental Media**

Diagnostic Supplemental Media contains all the necessary diagnostic programs and files required to test a particular resource. The supplemental is normally released and shipped with the resource as indicated on the diskette label. Diagnostic Supplemental Media must be used when the device support has not been incorporated into the latest Diagnostic CDROM.

This task processes the Diagnostic Supplemental Media. Insert the Supplemental Media when prompted, then press `Enter`. After processing has occurred, go to the Resource Selection list to find the resource to test.

**Notes:**
- This task is supported in **Standalone Diagnostics** only.
- Always process and test one resource at a time.
- Do not process multiple supplementals at a time.

More information on Diagnostic Supplemental Media can be found at the following link: [Diagnostic Supplemental Media](#)

**Run Diagnostics**

The Run Diagnostics task invokes the Resource Selection List menu. When the commit key is pressed, Diagnostics are run on all selected resources.

The procedures for running the diagnostics depends on the state of the Diagnostics Run Time Options. See [Display or Change Diagnostic Run Time Options](#) section.

**Run Error Log Analysis**

The Run Error Log Analysis task invokes the Resource Selection List menu. When the commit key is pressed, Error Log Analysis is run on all selected resources.
Save or Restore Hardware Management Policies (CHRP)

Use this Service Aid to save or restore the settings from Ring Indicate Power On Policy, Surveillance Policy, Remote Maintenance Policy and Reboot Policy.

**Note:** Runs on CHRP systems units only.

- **Save Hardware Management Policies**
  This selection writes all of the settings for the hardware management policies to the file:
  /etc/lpp/diagnostics/data/hmpolicies

- **Restore Hardware Management Policies**
  This selection restores all of the settings for the hardware management policies from the contents of the file:
  /etc/lpp/diagnostics/data/hmpolicies

This Service Aid may be accessed directly from the command line, by entering:
/usr/lpp/diagnostics/bin/uspchrp -a

Save or Restore Service Processor Configuration (RSPC)

**Attention:** This diagnostic task has been removed in AIX 5.2. The information has been retained for reference only.

Use this Service Aid to save or restore the Service Processor Configuration to or from a file. The Service Processor Configuration includes the Ring Indicator Power On Configuration.

**Note:** Supported on RSPC system units only.

- **Save Service Processor Configuration**
  This selection will write all of the settings for the Ring Indicate Power On and the Service Processor to the file:
  /etc/lpp/diagnostics/data/spconfig

- **Restore Service Processor Configuration**
  This selection will restore all of the settings for the Ring Indicate Power On and the Service Processor from the file:
  /etc/lpp/diagnostics/data/spconfig

SCSD Tape Drive Service Aid

This Service Aid provides a means to obtain the status or maintenance information from a SCSD tape drive. Only some models of SCSI tape drive are supported.

The Service Aid provides the following options:

- **Display time since a tape drive was last cleaned.**
  The time since the drive was last cleaned is displayed onto the screen. In addition, a message whether the drive is recommended to be cleaned is also displayed.

- **Copy a tape drive’s trace table.**
- **The trace table of the tape drive is written to diskettes.**
  The required diskettes must be formatted for DOS. Writing the trace table may require several diskettes.
  The actual number of required diskettes is determined by the Service Aid based on the size of the trace table. The names of the data files are of the following format:

  TRACE\[X\].DAT

  where X is the sequential diskette number. The complete trace table consists of the sequential concatenation of all the diskette data files.
• **Display or copy a tape drive’s log sense information.**

The Service Aid provides options to display the log sense information onto the screen, to copy it to a DOS formatted diskette or to copy it to a file. The file name **LOGSENSE.DAT** is used when the log sense data is written on the diskette. The Service Aid prompts for a file name when the log sense data is chosen to be copied to a file.

**SCSI Bus Analyzer**

This Service Aid provides a means to diagnose a SCSI Bus problem in a free-lance mode.

To use this Service Aid, the user should have an understanding of how a SCSI Bus works. This Service Aid should be used when the diagnostics cannot communicate with anything on the SCSI Bus and cannot isolate the problem. Normally the procedure for finding a problem on the SCSI Bus with this Service Aid is to start with a single device attached, ensure that it is working, then start adding additional devices and cables to the bus ensuring that each one works. This Service Aid works with any valid SCSI Bus configuration.

The SCSI Bus Service Aid transmits a SCSI Inquiry command to a selectable SCSI Address. The Service Aid then waits for a response. If no response is received within a defined amount of time, the Service Aid displays a timeout message. If an error occurs or a response is received, the Service Aid then displays one of the following messages:

• The Service Aid transmitted a SCSI Inquiry Command and received a valid response back without any errors being detected.
• The Service Aid transmitted a SCSI Inquiry Command and did not receive any response or error status back.
• The Service Aid transmitted a SCSI Inquiry Command and the adapter indicated a SCSI bus error.
• The Service Aid transmitted a SCSI Inquiry Command and an adapter error occurred.
• The Service Aid transmitted a SCSI Inquiry Command and a check condition occurred.

When the SCSI Bus Service Aid is entered a description of the Service Aid is displayed.

Pressing the Enter key displays the Adapter Selection menu. This menu allows the user to enter which address to transmit the SCSI Inquiry Command.

When the adapter is selected the SCSI Bus Address Selection menu is displayed. This menu allows the user to enter which address to transmit the SCSI Inquiry Command.

Once the address is selected the SCSI Bus Test Run menu is displayed. This menus allows the user to transmit the SCSI Inquiry Command by pressing the Enter key. The Service Aid then indicates the status of the transmission. When the transmission is completed, the results of the transmission are displayed.

**Notes:**

1. A Check Condition can be returned when there is nothing wrong with the bus or device.
2. The operating system does not allow the command to be sent if the device is in use by another process.

**Service Aids for use with Ethernet**

**Attention:** This diagnostic task has been removed in AIX 5.2. The information has been retained for reference only.

This selection provides a tool for diagnosing Ethernet problems. This Service Aid is used to exercise the Ethernet adapter and parts of the Ethernet network. The Service Aid works by transmitting a data block to itself. This Service Aid works with a wrap plug or with any valid Ethernet network and can be used as a tool to diagnose Ethernet network problems.
When the Ethernet Service Aid is executed, one of the following messages is returned:

- No errors occurred.
- An adapter error occurred.
- A transmit time-out occurred.
- A transmit error occurred.
- A receive time-out occurred.
- A receive error occurred.
- A system error occurred.
- Receive and transmit data did not match.
- An error occurred that could not be identified.
- The configuration indicates that there are no Ethernet adapters in this system unit.
- Another application is currently using the adapter.
- The resource could not be configured.

**Spare Sector Availability**

This selection checks the number of spare sectors available on the optical disk. The spare sectors are used to reassign when defective sectors are encountered during normal usage or during a format and certify operation. Low availability of spare sectors shows that the disk needs to be backed up and replaced. Formatting the disk does not improve the availability of spare sectors.

This task may be run directly from the command line. The following usage statement describes the syntax of the fastpath command:

**Usage:**

diag -T "chkspares"

**SSA Service Aids**

This Service Aid provides tools for diagnosing and resolving problems on SSA attached devices. The following tools are provided:

- Set Service Mode
- Link Verification
- Configuration Verification
- Format and Certify Disk

**Update Disk Based Diagnostics**

This Service Aid allows fixes (APARs) to be applied.

This task invokes the SMIT Update Software by Fix (APAR) task. The task allows the input device and APARs to be selected. Any APAR can be installed using this task.

**Update System Flash (RSPC)**

This selection updates the system flash for RSPC systems.

The user provides a valid binary image either on diskette or qualified path name. The diskettes can be in DOS or a backup format.

The flash update image is copied to the /var file system. If there is not enough space in the file system for the flash update image file, an error will be reported. If this occurs, increase the file size of the /var file system. The current flash image is not saved. The command automatically removes the /var/update_flash_image.
After user confirmation, the command will reboot the system twice to complete the flash update.

**Note:** Supported on RSPC system units only.

**Update System or Service Processor Flash (CHRP)**

This selection, located in the Microcode Tasks submenu, updates the system or service processor flash for CHRP system units.

Further update and recovery instructions may be provided with the update. It is necessary to know the fully qualified path and file name of the flash update image file that was provided. If the flash update image file is on a diskette, the Service Aid can list the files on the diskette for selection.

Refer to the update instructions, or the system unit’s service guide to determine the level of the system unit or service processor flash.

**Note:** Runs on CHRP system units only.

When run from online diagnostics, the flash update image file is copied to the /var file system. If there is not enough space in the /var file system for the flash update image file, an error is reported. If this occurs, exit the Service Aid, increase the size of the /var file system and retry the Service Aid. After the file is copied, a warning screen asks for confirmation to continue the update flash. Continuing the update flash reboots the system. The system does not return to diagnostics. The current flash image is not saved. After the reboot, the /var/update_flash_image can be removed.

When running from standalone diagnostics, the flash update image file is copied to the file system from diskette. The user needs to provide the image on a diskette since the user does not have access to remote file systems or any other files that are on the system. If enough space is not available, an error is reported stating additional system memory is needed. After the file is copied, a warning screen asks for confirmation to continue the update flash. Continuing the update flash reboots the system. The current flash image is not saved.

The update_flash command can be used in place of this Service Aid. It is located in the /usr/lpp/diagnostics/bin directory.

**Attention:** The update_flash command reboots the entire system. Do not use this command if more than one user is signed onto the system.

**7135 RAIDiant Array Service Aid**

The 7135 RAIDiant Array Service Aids contain the following functions:

- **Certify LUN**
  This selection reads and checks each block of data in the LUN. If excessive errors are encountered the user is notified.

- **Certify Spare Physical Disk**
  This selection allows the user to certify (check the integrity of the data) on drives designated as spares.

- **Format Physical Disk**
  This selection is used to format a selected disk drive.

- **Array Controller Microcode Download**
  This selection allows the microcode on the 7135 controller to be updated when required.

- **Physical Disk Microcode Download**
  This selection is used to update the microcode on any of the disk drives in the array.

- **Update EEPROM**
  This selection is used to update the contents of the EEPROM on a selected controller.
• Replace Controller
  Use this selection when it is necessary to replace a controller in the array.

## Application Test Units

Application Test Units (TU) are used by the Diagnostic Applications to test a device. Typically, due to either their large size or their functional composition, TUs are more appropriately written as applications as opposed to being included within device drivers.

This chapter defines requirements for Application Test Unit code and provides guidance for TU Developers who need to develop code for multiple target environments. The TU code should be developed in ANSI C language and according to generally accepted good programming practices, including, but not limited to:
- Modularity
- Readability
- Self Documenting
- Maintainability
- Re-entrant Capability

The use of assembler-level code is strongly discouraged, but may be necessary in certain cases where performance is critical to the effectiveness of the test function. Such code would not be considered portable and would have to be rewritten for the target platform.

The following topics are discussed in detail:
- Test Unit Definition
- Hardware Functional Coverage
- Test Unit Numbering
- Test Unit Code Device Open and Close
- Portability
- In-Service versus Out-of-Service Test Units
- Recommended General Structure of Test Unit Code
- Designing for Multitasking Environments
- Persistent Data and the TU_INFO_HANDLE
- Test Unit Call Interface
- Definition of TU_TYPE Input Structure
- Definition of TU_RETURN_TYPE Output Structure
- Return Codes
- Interrupt Handler Call Interface
- Interrupt Handling in Test Units
- Using the Interrupt Flag Bit Mask
- Programming Interfaces for TUs and Interrupt Handlers
- Configuration Services Device Attributes
- Message Handling
- Signal Handling
- Definition of EXECTU()
- PCI Configuration Space for I/O Devices
- Test Unit 64-bit Porting Guide
- Microcode Download/Display Requirements for Test Units
- Enhanced Error Handling Option
Test Unit Definition
Fundamental to the Test Unit methodology is a basic, modular building block that is referred to as a Test Unit. A test unit is a single operation performed on the system or subsystem under test. Most often this is an individual function test, such as a register read/write test. Several basic assumptions are made for the test units:

- Only one modular test function is performed in each individual test unit.
- Test units are numbered, and the calling application specifies the number of the test unit it wishes to execute.
- No environmental specific code is allowed in a test unit. This specifically includes user interface calls. Also, device-access methods such as reads or writes are done with generic function calls, which can then be defined in a different source file and coded, if necessary, to meet the specific requirements of the target environments.
- Test units are grouped appropriately in source files. This allows custom building of executable libraries to meet the requirements of the target environments.
- In cases where the same test unit may be used to test hardware in different ways based on some control variables (for example, speed or mode settings), that test unit may be used to represent several "logical" test units, each with a different test unit number. When the test unit is called, it would interpret the test unit number requested and set the control variables appropriately.

Hardware Functional Coverage
The Test Unit package should be designed and implemented such that if the TUs are run in the recommended order as documented, then a minimum coverage of 95% of the hardware function is achieved.

Test Unit Numbering
Test Units should be numbered according to some logical sequence, which is determined by the TU Developer. Zero should not be used as a TU number. The allowable range for TU numbers is 1 through 61439 (1 through EFFF hex). This numbering requirement must be respected even though the TU member of the tucb header structure is defined as a 32 bit integer. It is desirable that a numbering scheme be developed by the TU Developer allowing TUs to be executed in sequential numerical order when executing them as designated. This might include spacing the TUs so that future TUs can be inserted into the number sequence, where appropriate.

Test Unit Code Device Open and Close
Before a device can be tested by one of the test units, it must be opened for access through the interfaces defined in "Programming Interfaces for TUs and Interrupt Handlers". Also, when testing is complete, the device must be closed and restored to its original state. The opening and closing of the device for testing presents some problems that must be accounted for in the design of the Test Unit library for the device:

- Errors may occur on the open and close operation, and these must be presented back to the calling applications in a form those applications know how to handle; that is, test unit results.
- Since the calling application will typically run through all or most of the Test Units for a given device, the performance penalty of opening and closing the device for each call to a Test Unit is prohibitive.
- Under different conditions, test units may be run in different combinations and sequences, so the calling application must be able to call the functions which do device open and close independent of the other test functions.

Test Unit Conventions
To provide a standard solution for handling the above problems, the following conventions for Test Units within a specific device library are required:

1. There must be a Test Unit number 1, referred to as TU_OPEN, which includes functions to initialize data structures, place the device in the correct state for diagnostics, and open the device for testing. It
does not perform any other test functions. Any error conditions are returned as diagnostic results. The define value TU_OPEN should be used as the numerical identifier for this Test Unit.

Specifically, **TU_OPEN** performs the following:

- a. Sees that the TU_INFO_HANDLE parameter is set to NULL, allocates a memory buffer to hold persistent data, and assigns TU_INFO_HANDLE to that address. For more information, see "Persistent Data and the TU_INFO_HANDLE".

- b. Reads needed device attribute information by making calls to the configuration services (pdiag_cs_get_attr) and places appropriate information into the pdiagex_dds_t structure that is passed as a parameter on the pdiag_open call.

- c. Calls pdiag_diagnose_state to place the device into a testable state.

- d. Calls pdiag_open to open the device for testing, and loads the interrupt handler, if one exists.

- e. Assuming all the above functions are performed without error, returns a value of "0" as the major return code.

2. There must be a Test Unit number 61439 (0xEFFF hex), referred to as **TU_CLOSE**, which closes the device and restores the device to the original state it was in prior to diagnostics being invoked. The define value TU_CLOSE should be used as the numerical identifier for this test unit.

Specifically, **TU_CLOSE** performs the following:

- a. Calls pdiag_close to close the device, and unloads the interrupt handler.

- b. Calls pdiag_restore_state to return the device to the state it was in prior to **TU_OPEN**.

- c. Frees any memory buffers that were allocated by **TU_OPEN**. For the most part, the buffers that need to be freed are "secondary" persistent data buffers, pointed to by pointers in TU_INFO_HANDLE.

- d. Assuming all the above functions are performed without error, returns a value of "0" as the major return code.

- e. A valid diagnostic sequence consists of a call to Test Unit **TU_OPEN**, some arbitrary number of calls to Test Units other than **TU_OPEN** or **TU_CLOSE**, and then a final call to Test Unit **TU_CLOSE**.

### Portability

With today’s systems, multiple operating systems are typically supported on a single hardware platform. Since these systems usually share the same hardware features, diagnostics need to be written to support hardware failure analysis that works within any of these operating environments. For this reason, all TU packages must be designed with portability in mind.

Besides the operating environment differences, there is also the need for different types of user interfaces for the different execution environments. For instance, system diagnostics for the field may use a different interface than the hardware exerciser used in the design verification test.

By ensuring that the TU package performs no interaction with the user (output to screen and input from keyboard), one third of the problem will have been solved. Then all the invocations of the TUs will be made through one interface, and different types of user interfaces can be developed with no need to change the TU package.

Another third of the problem concerns how the device gets accessed through the operating environment. Since different operating environments have different device drivers (for example, UNIX® drivers, DOS/WIN drivers, Firmware based, or generic I/O, there must be a way to isolate the functional test from the burden of knowing what driver/environment is being used for access. Therefore, standard device-access routines are needed to perform the device accesses on the functional test’s behalf. The device accesses typically needed for functional tests are:

- Device Open
- Read
The interface of these routines must be independent of the underlying device-access method (that is, execution environment) by design, and must not change across operating environments. The internals of these routines will change per operating environment, using the appropriate system/driver calls to accomplish the device-access requests on the functional tests’ behalf.

**In-Service versus Out-of-Service Test Units**

The architecture described in this document is primarily for the creation of “out-of-service” Test Units, meaning that the device being tested is not available for any other use by the operating system while it is under test. In high-availability systems, however, it is often desirable to have Test Units which can be used while the device is “in-service.” This may be especially true for devices which can have partial failures; for example, DASD media, RAID, memory/cache arrays, and multi-port adapters. A variation of In-Service diagnostics can sometimes be done with an Out-of-Service Test Unit that takes over the device for such a short period of time that no service outage is detected.

Test units designed to be run truly concurrently with other operations on the same hardware component will, in general, have to perform their testing through the “normal” functional device driver installed by the operating system. Because the device driver model tends to be unique to each operating system, the Test Unit written to that interface may not be easily portable to other operating systems. However, proper structuring of the Test Unit library, as discussed below in [“Recommended General Structure of Test Unit Code,”](#) will help isolate into a single source file those functions which must be modified.

**Recommended General Structure of Test Unit Code**

The TU environment specified in this document is designed to provide source code portability of TUs across multiple operating environments. TUs should only use the device and system interfaces specified in this document to ensure portability. However, experience has shown that it is good programming practice to isolate and abstract external functions so that any problems in porting can be corrected within a single source code file. For this reason, it is strongly recommended that TU developers include a special source file in their TU library for the purpose of providing that isolation and abstraction. The following describes a recommended implementation of that source file, given to help promote consistency in TU development. The consistency is very important for long-term maintenance of the Test Unit code.

TU libraries should include a C source file called `interface.c`, which provides a set of abstracted device functions that can be used by the actual TU functions. The following is a list of functions that should be implemented within the `interface.c`.

<table>
<thead>
<tr>
<th>TU Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dd_open</td>
<td>Prepares a device for testing and obtains needed device attributes.</td>
</tr>
<tr>
<td>dd_close</td>
<td>Cleans up after testing.</td>
</tr>
<tr>
<td>dd_read</td>
<td>Performs a read operation.</td>
</tr>
<tr>
<td>dd_write</td>
<td>Performs a write operation.</td>
</tr>
<tr>
<td>dd_dma</td>
<td>Initializes, pins, and cross-memory attaches the user buffer for a DMA operation.</td>
</tr>
<tr>
<td>dd_dma_enable</td>
<td>Enables/Disables a DMA operation.</td>
</tr>
<tr>
<td>dd_dma_cleanup</td>
<td>Deallocates any resources previously allocated for a DMA operation.</td>
</tr>
<tr>
<td>dd_interrupt</td>
<td>Processes interrupt conditions.</td>
</tr>
</tbody>
</table>

As illustrated below, these functions should provide mappings to one or more of the services described in [“Programming Interfaces for TUs and Interrupt Handlers”](#).
The figure also illustrates how TU libraries should include a C source file that implements the `executu()` interface, which provides the program entry point for the TU library, decodes the specified TU number to the correct internal function, and calls that function.

**Designing for Multitasking Environments**

Test units should be designed with rules of re-entrance in mind. Although it is unlikely that a given set of Test Units could be run simultaneously against the same device, it is possible that more than one of the same type of device (or devices which are tested by the same TU code) exists in the system. Since it may be desirable to run the Test Units concurrently as part of a system exerciser or a stress test for a specific subsystem, it is possible that the same TU code may be run in different threads under the same process. The use of static variables in this case could lead to data conflicts between the multiple instances of TU code execution.

**Persistent Data and the TU_INFO_HANDLE**

Because of the requirement to allow multi-threaded, simultaneous execution of Test Units, the TU functions must be written to be re-entrant, implying that statically defined variables or structure are not allowed.

**Note:** Static constant values are not a problem.

To illustrate the problem, imagine two threads of execution calling the same TU to run simultaneously against two device instances of the same type. Values stored in static variables would get changed in both threads of execution, probably leading to a program failure. Therefore, all variables and structures must be
either defined locally as stack variables, or created using allocated memory. Without static variables, it is
difficult to retain any data around from one execution of a TU to the next.

The intent of the TU_INFO_HANDLE pointer in the `exectu()` interface is to provide the TU writer with a
pointer to a data buffer that will persist across multiple execution calls to specific Test Units. On the first
call to a TU library, the TU_INFO_HANDLE pointer will be set to NULL. The first TU, TU_OPEN, must
allocate the buffer and set the TU_INFO_HANDLE pointer. Data that the TU writer wants to have persist
(for example, device attribute information) can then be placed within that buffer, and the pointer to the
buffer will be passed back on each subsequent call to the TU library.

Because the data buffer remains allocated after the TU returns control to the calling application, it is the
responsibility of the calling application to free the buffer any time that a premature termination is required,
or after it calls the last TU (TU_CLOSE).

Data that should be kept in the persistent data buffer includes:
- The `pdiagex_dds_t` structure which contains several device attributes and is used as a parameter to the
  `pdiag_open` call.
- The PDIAG_INFO_HANDLE returned from the `pdiag_open` call, which is used as an input parameter to
to all the other device operation functions.
- An indicator of the state of the device (DIAGNOSE or NORMAL)
- Other device-attribute information obtained from Configuration Services using the `pdiag_cs_get_attr`
  function (to avoid the overhead of rerequesting it for each TU call).
- Any other information the TU writer would like to have persist from one call to the next.

Test Unit Call Interface

To execute test units, a C language function with the name `exectu()` has been defined to provide the
interface between the test unit code and the managing application. The definition of this interface has been
developed to:
- Hide the complexity of the structures and protocols used in performing functional tests
- Provide a uniform interface for all the different management applications that may invoke the test unit
code.

See the section "Definition of EXECTU"

Definition of TU_TYPE Input Structure

The `exectu()` interface is dependent on the definition of a Test Unit Control Block (TUCB) structure. The
TUCB is defined as a C language data type called TU_TYPE, and is located in the `diag/tucb.h` header
file. This header file must be used without modification and included in each source file using the structure.

To make the test unit functions available to a wide range of managing applications, this TUCB structure
must not deviate from the defined structure. No new data types or structures may be added. Each test unit
should be self-sufficient in the function provided. The data types OUTPUT_DATA and INPUT_DATA are
declared as 'void' in the `diag/tucb.h` file. If these structures are to be used, two header files are required
redefine these parameters:
- The `{DEVICE}_err_detail.h` file should be used to define device specific error log detail output data
  (OUTPUT_DATA).
- The `{DEVICE}_input_params.h` file should be used to define device specific input parameter data
  for a test unit (INPUT_DATA).

Both header files (if used) should be included before the `diag/tucb.h` file.

The TU_TYPE structure is specified as follows:
typedef struct tucb_t {
    char *resource_name;
    TU_INPUT_TYPE parms;
} TU_TYPE;

The resource_name is a string containing the name of the hardware or physical device (as defined by the
operating system) on which to run the test unit. TU_INPUT_TYPE is a substructure of TU_TYPE, and
contains several input parameters, as specified in the following:

typedef struct tucb_in_t {
    ulong tu;
    ulong loop;
    OUTPUT_DATA *data_log;
    ulong data_log_length;
    INPUT_DATA *tu_data;
    ulong tu_data_length;
    FILE *msg_file;
} TU_INPUT_TYPE;

See "Definition of EXECTU()" for structure member definitions.

Note: For most applications, the TU number and loop count are the only parameters required. However,
this interface allows for an open way of passing special parameters into the Test Units and
receiving detailed data back out, to allow for specialized testing environments.

Using such data requires specific knowledge about the Test Unit design in the calling application, and does
not allow for generic diagnostic handling, as would be required from a system management application.
However, this design would allow a remote diagnostic application, which could have detailed diagnostic
design knowledge, to work through a local agent function which only has generic diagnostic knowledge.
The local agent would only have to allocate buffers of the requested size, and pass data between the Test
Units and the remote diagnostic application.

Definition of TU_RETURN_TYPE Output Structure
The exectu() interface expects, as a return value, a unsigned long major_rc return code value. As an
extension of this return value, a Test Unit Control Block (TUCB) return structure is included as a third
argument to the exectu() function call. The TUCB return structure is defined as a C language data type
called TU_RETURN_TYPE, and is defined in the diag/tucb.h header file. This header file must be used
without modification and included in each source file where the structure is used.

typedef struct tucb_out_t {
    ulong major_rc;
    ulong minor_rc;
    ulong actual_loop;
    ulong data_log_length;
    ulong severity;
} TU_RETURN_TYPE;

See "Definition of EXECTU()" for structure member definitions.

Return Codes

major_rc
The major_rc return value from the exectu() function should indicate the success or failure of the TU
which was executed. If all testing is successful, it should return a value of zero (0), otherwise a non-zero
value should be returned corresponding to a specific value. A managing application uses the major_rc
return code to determine the flow of the diagnostic procedure, and to look up the appropriate card level
Field Replaceable Unit (FRU) or FRUs to be replaced. To satisfy the failure-isolation requirements of all
managing applications, the return codes should be designed to be as granular as possible to provide
maximum fault isolation. For most purposes, this means attempting to isolate to a single FRU.
Note: When defining major_rc return codes, keep the following in mind:

- Never return memory offset information in the return code.
- Do not return any detailed information, such as failing bits, through the return code. Instead, use the OUTPUT_DATA error log.

minor_rc
The minor_rc return value is used to pass back a more specific error indication, and would typically be provided as an aid for fault isolation within a FRU, perhaps down to modules or I/O lines. This information is intended for use in bring-up and debug, and in manufacturing, to point to a specific hardware defect. Used in conjunction with the OUTPUT_DATA error log, the TU writer should be able to pass back enough information to isolate to a failure to whatever level is needed. However, most management applications will only be interested in the major_rc return value.

Interrupt Handler Call Interface
The diagnostic interrupt handler function for a device must be packaged in an executable module separate from the Test Unit library. This module is loaded into the operating system and registered with the diagnostic system services when the TU_OPEN calls the pdiag_open function.

When the services receive an interrupt, control is passed to these "second-level" interrupt handlers in sequential order. Each interrupt handler reads the status of its respective adapter to see if it was the source of the interrupt. If the Test Unit is waiting for the interrupt by calling the pdiag_dd_watch_for_interrupt service, the sleep_flag will be set to 1, indicating that the interrupt handler should do a pdiag_dd_interrupt_notify when it has completed.

Interrupt handlers can use the device methods to read and write operations on the device. Typically, they will read registers on the device to obtain more information about the interrupt, and write registers (if necessary) to clear the interrupt condition. The content of any data passed back to the TU through the data_area buffer, and whether the TUs even wait for interrupts, is a decision left to the designer of the TUs and interrupt handler. That decision depends upon the operation of the specific device and how it is being tested.

Syntax
The function entry prototype for an interrupt handler is as follows:

```c
int device_interrupt (  
   PDIAG_INFO_HANDLE  *handle,  
   pdiag_addr_t data_area,  
   int32 *interrupt_flag,  
   uint32 sleep_flag,  
   uint32 *sleep_word )
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>Pointer to a handle for use in device operations</td>
</tr>
<tr>
<td>data_area</td>
<td>Buffer area where the interrupt handler can store information that the Test Unit can review after interrupt processing is complete.</td>
</tr>
<tr>
<td>interrupt_flag</td>
<td>Bit field indicating which interrupt occurred</td>
</tr>
<tr>
<td>sleep_flag</td>
<td>Boolean value to indicate whether the waiting Test Unit should be notified</td>
</tr>
<tr>
<td>sleep_word</td>
<td>Semaphore that the Test Unit is waiting for, used as a parameter to the pdiag_dd_interrupt_notify service</td>
</tr>
</tbody>
</table>
Interrupt Handling in Test Units

A typical sequence of events in the functional flow of a Test Unit is to set up a device operation through reads and writes to the device address space, and then wait to receive an interrupt from the device to indicate that an operation has completed or needs attention. Since interrupt handling is device-specific and part of the test process, an interrupt handler function must be provided in addition to the Test Unit library. When a device is opened for testing by Test Unit 1 (TU_OPEN), an interrupt handler may be loaded (if one is needed) by passing an interrupt handler module name as one of the parameters on the `pdiag_open` system service. A data buffer address is also passed as part of the input to the `pdiag_open` function, so the device methods know which interrupt handler to use, as well as where to pass back data from the interrupt handler.

The purpose of the interrupt handler function is to receive the interrupt indication, possibly gather some information from the device, clear the interrupt condition on the device, and notify a waiting Test Unit that the interrupt has occurred. Clearing of the interrupt condition is critical, because the interrupt handler will be called continuously as long as the interrupt condition exists. Since this function is called to handle a specific device I/O interrupt, the information it gathers from the device is useful in diagnosing the device behavior. The interrupt handler puts this information into the data buffer area (defined at device-open time), where the waiting Test Unit can access it for analysis.

The basic flow of interrupt processing is shown in the “Interrupt Processing in Test Units” illustration. The flow of events is as follows:

1. An `execu()` call is made to Test Unit 1 (TU_OPEN), which calls `pdiag_open` to open the device for testing. Included in the input information passed to `pdiag_open` is the name of the interrupt handler module and the address of a memory-allocated data buffer area.
2. A Test Unit is started, which performs some operations on the device, and then calls `pdiag_dd_watch_for_interrupt` to wait for a response in the form of a device interrupt (or a time-out if no interrupt occurs).
3. The device-methods layer receives an interrupt indication from the operating system.
4. The device-methods pass control to the registered interrupt handler.
5. The interrupt handler function gathers data from the device and places it in the data buffer area, clears the interrupt, and releases the Test Unit from its WAIT state.

6. The interrupt handler completes and returns to the caller (the device methods).

7. The Test Unit continues execution by processing the data returned from the interrupt handler.

8. When testing is completed, a call is made to Test Unit 0xEFFF (TU_CLOSE), which calls `pdiag_close` to close the device and unload the interrupt handler.

The cycle of device setup and wait for interrupt can be repeated as often as necessary during the execution of the Test Units. Registration of the interrupt handler only needs to be done once, at the time when the device is opened for testing. However, different interrupt handlers could be used (if necessary) by closing the device, then reopening the device with a different interrupt handler module-name parameter.

### Using the Interrupt Flag Bit Mask

The `interrupt_flag` parameter to the interrupt handling routine and the `flag_mask` parameter on the `pdiag_dd_watch_for_interrupt` system service are used by the Test Unit and interrupt handler to communicate the type of interrupt that occurred, and which types of interrupts the Test Unit wants to know about. The bit fields within these words can be defined in whatever way the TU developer wants to assign them, based on the device involved and how many different interrupt types it can surface. However, it is important to understand how these parameters should be used.

When an interrupt handler is called as the result of an interrupt condition, it should examine its device to see which type of interrupt, if any, occurred on that device. If it detects no interrupt condition, the `interrupt_flag` should be set to 0 before it returns. If it does detect an interrupt condition, then it should set an appropriate bit equal to 1 in the `interrupt_flag` before it returns.

A TU waits for an interrupt condition to occur by calling the `pdiag_dd_watch_for_interrupt` service, and one of the parameters to that function is a `flag_mask` word. This is defined as a bit mask, using the same bit definitions as in the interrupt handler, to indicate the interrupt types for which the TU wants to watch. It does this by setting one or more bit values equal to 1, where each bit represents an interrupt type. The `pdiag_dd_watch_for_interrupt` will not return until either an appropriate interrupt is detected (essentially determined by a non-zero result when "and"ing the `flag_mask` and the `interrupt_flag` 0 values), or until the time limit is reached.

**Note:** If the Test Unit writer wants to watch for more than one interrupt type, but also needs to know which specific interrupt occurred, the writer should define a structure element in the `data_area` buffer where the interrupt handler can pass back that information.

### Example

```c
#define Int_A 80000000 /* Common defines used by both the TU and */
#define Int_B 40000000 /* interrupt handler */
#define Int_C 20000000
```

Assume TU calls `pdiag_dd_watch_for_interrupt` with:

```c
flag_mask = Int_A | Int_B
```

**Case 1:**

1. Interrupt received
2. Interrupt handler reads device, sees Interrupt C, sets:
   ```c
   interrupt_flag = Int_C
   ```
3. `pdiag_dd_watch_for_interrupt` does not return until timeout occurs.

**Case 2:**

1. Interrupt received
2. Interrupt handler reads device, sees interrupt A, sets:
   \[ \text{interrupt\_flag} = \text{Int\_A} \]
3. `pdiag_dd_watch_for_interrupt` returns

**Case 3:**
1. Interrupt received
2. Interrupt handler reads device, sees both interrupt B and C, sets:
   \[ \text{interrupt\_flag} = \text{Int\_B} \land \text{Int\_C} \]
3. `pdiag_dd_watch_for_interrupt` returns

### Programming Interfaces for TUs and Interrupt Handlers

System interface calls and use of header files should conform to the X/Open Portability Guide Issue 4 standards. This ensures portability to other platforms meeting the same standards.

The following table lists the standard set of services available to TU developers. Using only these services provides portability of TUs to other platforms where this diagnostic infrastructure is supported. See "Diagnostic Kernel Extension Interfaces" for more information on these functions, their input parameters, and the function prototypes.

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
<th>Usable by:</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pdiag_open</code></td>
<td>Opens a device for testing</td>
<td>TU</td>

</tbody>
</table>
**Configuration Services Device Attributes**

The configuration data services provided by the `pdiag_cs_*` functions (described in the previous table) define the interface by which the TU developer may obtain information about the device under test. The table below lists the standard attributes which may be available for a given device; however, not all attributes are supported for all devices, since some are specific to particular device types.

Normally, the TU developer should use this service to gather the required attribute information during the call to Test Unit `TU_OPEN` (the Test Unit which opens the device for testing), and save this device information for reference during subsequent Test Unit calls. This avoids the performance overhead of calling the configuration services many times during the execution of a set of Test Units.

<td>Slot number of adapter (for MCA, actual slot number, for PCI, device number)</td>
</tr>
</tbody>
</table>

**Message Handling**

In general, there should be no `printf()` or `fprintf()` calls imbedded in TU code which is delivered for production use. This includes debug messages, execution-progress messages, and so on. However, it is understood that such practices are common and useful during the initial code development, and sometimes desirable at a later time when something breaks. Therefore, to satisfy both requirements, the messages should be allowed to be conditionally compiled in and out of the code. To allow the calling application to redirect the messages to any file, including `stdout`, only the `fprintf()` call should be used.

Then, to conditionally compile the messages, the following convention should be followed:

In one of the include files, define the following PRINT macros conditionally with the standard conditional flag `TU_DEBUG_MSG`.

```c
#ifndef TU_DEBUG_MSG
#define PRINT(args) fprintf(args)
#else
#define PRINT(args) #endif
```

60  AIX Version 6.1 Understanding the Diagnostic Subsystem for AIX
Next, use the "msg_file" pointer in the TUCB structure definition which determines where messages will be sent.

Then, at any place in the code where a message should be output, use the PRINT macro. The calling application would then set the "msg_file" parameter to stdout in order to have messages directed to a terminal or monitor. Alternatively, to have messages directed to a file, the calling application would use the fopen() function to open a file and set "msg_file" to the pointer returned from this call.

For example, you want to print the message "Hello, World number 1", and tucb_ptr is a pointer to the TU_TYPE structure passed by the application, and w_num is a variable with a value of 1. You could then insert, at an appropriate place in the TU code, a line like the following:

PRINT((tucb_ptr->parms.msg_file, "Hello, World number %d", w_num));

**Note:** The double parentheses are required to pass variable-length argument lists through the PRINT macro to the fprintf() function.

**Signal Handling**

In general, signal handling is the responsibility of the DA. When a signal to terminate is caught, the signal handler must start TU_CLOSE through the exectu() interface, so that a proper cleanup of the device is performed and a release of resources occurs. TU_CLOSE should be started only if TU_OPEN has already been called successfully.

**Definition of exectu()**

**Purpose**

Executes test unit (TU) bound into a Diagnostic Application (DA).

**Syntax**

```c
#include <diag/tucb.h>
ulong exectu ( TU_TYPE *tucb_ptr, TU_INFO_HANDLE *tu_handle, TU_RETURN_TYPE *tu_rc)
```

**Description**

The exectu subroutine runs an TU referenced by the test unit control block. The test units are normally built and packaged as a loadable library. The device to be tested by the test unit is referenced by a character-string designator indicating the device instance.
## Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tucb_ptr</td>
<td>Pointer to the test-unit control block. This structure is defined in <code>diag/tucb.h</code> file.</td>
</tr>
</tbody>
</table>

```c
typedef struct tucb_t {
    char  *resource_name;
    TU_INPUT_TYPE parms;
} TU_TYPE;
```

where `TU_INPUT_TYPE` is as follows:

```c
typedef struct tucb_in_t {
    ulong tu;
    ulong loop;
    OUTPUT_DATA *data_log;
    ulong data_log_length;
    INPUT_DATA *tu_data;
    ulong tu_data_length;
    FILE *msg_file;
} TU_INPUT_TYPE;
```

- **tu**
  - Test-unit number of the test unit to run.

- **loop**
  - Indicates the number of times the test unit should be run provided that an error does not occur.

- **data_log**
  - Error details log and or output data log. This log is device specific and is defined by the `{device}_output_data.h` file. It should point to an empty array of structures and then filled in with output or error detail data by the test unit(s). This parameter should be initialized by the calling application if intended to be used.

- **data_log_length**
  - Size of the data_log structure. This field is used when passing the tucb data to a remote managing application. This number is initialized by the calling application by calculating the size of the data structure to be filled in and multiplying it by the number of records to be logged. The test unit calculates the number of records by dividing this number by the size of the intended OUTPUT_DATA structure to be used. A `data_log_length` value of zero results in no data being logged to the data_log.

- **tu_data**
  - Input parameter to be used to pass extra input data to the test units. This parameter must only be used as special case scenarios. It is intended for special applications such as manufacturing or hardware exercisers.

- **tu_data_length**
  - Size of the tu_data structure. This field is used when passing the tucb data to a remote managing application. This number is initialized by the calling application by calculating the size of the data structure to be filled in and multiplying it by the number of records to be logged. The test unit calculates the number of data records by dividing this number by the size of the intended INPUT_DATA structure to be used.

- **tu_handle**
  - Pointer to a block of data that the TUs need to have persist between subsequent calls to the TU library. Content and layout of the persistent data is a decision left to the TU writer, but there are certain data structures which should be kept here, as described in the next section. Pointer variable is defined in the diagnostic application, but it is set by TU_OPEN to point to a memory buffer allocated by the TU_OPEN code. This structure is defined in `diag/tucb.h` file.
Parameter  

*tu_rc*  

**Description**  

Pointer to the test-unit control block return code structure. This structure is defined in `diag/tucb.h` file.

```c
typedef struct tucb_out_t {
    ulong major_rc;
    ulong minor_rc;
    ulong actual_loop;
    ulong data_log_length;
    ulong severity;
} TU_RETURN_TYPE;
```

- **major_rc**  
  Major return code. Used for FRU isolation.

- **minor_rc**  
  Minor return code. Used for more granular detailed fault isolation.

- **actual_loop**  
  Indicates the number of times the test unit ran.

- **data_log_length**  
  Returns the total number of data log records that have been recorded.

- **severity**  
  Indicates the severity of a diagnostic failure.

**Return Value**

The *major_rc* return code is defined as the output from a test unit. This is the same value contained in the `TU_RETURN_TYPE` structure.

Upon successful completion with no failure, a value of 0 should be returned in the *major_rc* field.

**PCI Configuration Space for I/O Devices**

There are several writable fields in the standard PCI Configuration Header for PCI devices. They are:

- Command Register
- Latency Timer
- Cache Line Size
- Base Address Registers
- Expanded ROM Base Address
- Interrupt Line

Some of these are written by the firmware and should never be changed by the device driver. The PCI Configuration Header Programming Table must be followed when programming the PCI Configuration Header registers.
### PCI Configuration Header Programming Table

Test Unit 64-bit Porting Guide

Changes to the pdiagex kernel extension running under a 64-bit kernel were designed with the test unit developer in mind. Most of the changes required to port the test units are done at the Second Level Interrupt Handler (SLIH) level. For a test unit developer that has followed the architecture specified in this document, the changes are minor and will require minimal testing.

Before porting an existing set of test units, it is important to understand the test units application environment as well as the 64-bit C language data model and how it differs from the 32-bit model.

Test units execute as 32-bit applications under a 32-bit kernel and therefore only use 32-bit kernel extensions (pdiagex). This porting guide describes the required changes to the test units and SLIH in order to function under a 64-bit kernel. The test units will continue executing as 32-bit applications: only the SLIHs will be 64-bit applications.

C Language Data Model

The C language data model used in the 32-bit and 64-bit operating system environments are defined in the following table. You must consider the size of the data passed from the Test Units to the SLIHs and back, since sizes can change as they are passed from one environment to the other. Use special care when passing information in the form of structures or pointers.

<table>
<thead>
<tr>
<th>C Type</th>
<th>32-bit Data Size</th>
<th>64-bit Data Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>char</td>
<td>8 bits</td>
<td>8 bits</td>
</tr>
<tr>
<td>short</td>
<td>16 bits</td>
<td>16 bits</td>
</tr>
<tr>
<td>int</td>
<td>32 bits</td>
<td>32 bits</td>
</tr>
<tr>
<td>long</td>
<td>32 bits</td>
<td>64 bits</td>
</tr>
<tr>
<td>long long</td>
<td>64 bits</td>
<td>64 bits</td>
</tr>
<tr>
<td>pointer</td>
<td>32 bits</td>
<td>64 bits</td>
</tr>
</tbody>
</table>

Makefile

To support 32-bit and 64-bit SLIHs, the SLIH Makefile has to be modified to build two executables; one for 32-bits that will remain named as it is today and one for the 64-bit SLIH which will have 64 appended to the name.

File Names | Syntax | Example |
-----------|--------|---------|
32-bit     | filename | fcphal_intr |
64-bit     | filename64 | fcphal_intr64 |

Makefile Source

Here is an example of what a common source 32-bit and 64-bit SLIH Makefile might look like:

Note: Replace the environment variables and file names with your own names to customize this example for your own use.

```bash
.TU_VPATH = ${MAKETOP}/bos/diag/tu/tu_dir
```

VPATH  = ${MAKETOP}bos/kernel/exp:${MAKETOP}bos/kernext/exp:$TU_VPATH

# 32-bit version of load object
# KERNEL_EXT  = your_intr

# 64-bit version of load object
# KERNEL_EXT64 = your_intr64

IDIR    = /usr/lpp/diagnostics/slih/

# install list containing 32-bit and 64-bit version
# ILIST    = your_intr your_intr64

OPT_LEVEL  = -qlist -qsource

# entry point, import and export files for 32-bit version
# your_intr_DEPENDS = your_intr.exp
your_intr_ENTRYPOINT = your_interrupt
your_intr_IMPORTS = -bI:pdiagex.exp
your_intr_EXPORTS = -bE:your_intr.exp

# entry point, import and export files for 64-bit version
# (common with 32-bit version)
# your_intr64_DEPENDS = your_intr.exp
your_intr64_ENTRYPOINT = your_interrupt
your_intr64_IMPORTS = -bI:pdiagex.exp \  
                        pdiagex64.exp
your_intr64_EXPORTS = -bE:your_intr.exp

# object list definition for 32-bit version
# your_intr_OFILES = your_intr.o

# object list definition for 64-bit version (common objects
# across 32-bit and 64-bit versions), with 64-bit objects
# renamed to .64o
# your_intr64_OFILES = your_intr.64o

INCFLAGS = -I${MAKETOP}/bos/diag/tu/tu_dir \ 
           -I${MAKETOP}bos/usr/include
LIBS     = ${KERNEXT_LIBS}

.include <$RULES_MK>

SLIH Conversion Tips
To achieve a clean SLIH conversion, pay special attention to the following:

- Any source code that assumes that int, long and pointer types are the same size must be corrected (reshaped) for 64-bit environment.
- Review any type casting, since the underlying data types may have changed.
- Make sure that any data structures containing long types and pointers are checked for sizes, especially data passed between test units and SLIHs (data_area). Refer to the C Language Data Model table. Also see Interrupt Handler Call Interface to make sure the data_area contains the proper data types.

When long types or pointers (or both) are passed in this structure, the structure must be reshaped before it is used by the SLIH.
• Use system-derived types for type declarations whenever possible.

**SLIH Conversion Required Changes**

The following required changes must be applied to all SLIHs being ported to 64-bit kernel:

1. **Performing Read Operations to a Device**
   
   All instances of `pdiag_dd_read` will have to be duplicated with `pdiag_dd_read_64` for 64-bit. Every place where `pdiag_dd_read` is used for a 32-bit SLIH, a `pdiag_dd_read_64` will be used for a 64-bit SLIH. This will be accomplished by using conditional preprocessor compiler statements (`#ifdef`).

   Here is an example of what a common source 32-bit and 64-bit read call might look like:

   ```
   #ifdef __64BIT_KERNEL
     rc = pdiag_dd_read_64(pdiagex_handle, IOSHORT16, io_addr, &datas, &flags);
   #else
     rc = pdiag_dd_read(pdiagex_handle, IOSHORT16, io_addr, &datas, &flags);
   #endif
   
   Notes:
   a. The `__64BIT_KERNEL` compiler directive is defined for 64-bit kernel compilers, therefore the user will not need to define it.
   b. Special case for IOLONG32 reads, the data has to be shifted 32-bits right after the function call, such as, `data = data >> 32;`.
   c. The `pdiag_dd_read_64` function is used in kernel environment only, therefore the intrlev flag must always be set to INTRKMEM.

2. **Performing Write Operations to a Device**
   
   All instances of `pdiag_dd_write` have to be duplicated with `pdiag_dd_write_64` for 64-bit. Every place where `pdiag_dd_write` is used for a 32-bit SLIH, a `pdiag_dd_write_64` will be used for a 64-bit SLIH. This will be accomplished by using conditional preprocessor compiler statements (`#ifdef`).

   Here is an example of what a common source 32-bit and 64-bit write call might look like:

   ```
   #ifdef __64BIT_KERNEL
     rc = pdiag_dd_write_64(pdiagex_handle, IOLONG32, io_addr, &datal, &flags);
   #else
     rc = pdiag_dd_write(pdiagex_handle, IOLONG32, io_addr, &datal, &flags);
   #endif
   
   Notes:
   a. The `__64BIT_KERNEL` compiler directive is defined for 64-bit kernel compilers, therefore the user will not need to define it.
   b. The `pdiag_dd_read_64` function is used in kernel environment only, therefore the intrlev flag must always be set to INTRKMEM.

3. **SLIH function prototype**
   
   The SLIH function prototype requires change in the type declaration for `*sleep_word` and `sleep_flag` as follows:

   ```
   int your_interrupt(pdiag_info_handle_t pdiagex_handle, char *data_area, int *interrupt_flag,
   #ifdef __64BIT_KERNEL
     long sleep_flag, long *sleep_word)
   #else
     int sleep_flag, int *sleep_word)
   #endif
   ```

Microcode Download/Display Requirements for Test Units
Any adapter or device that has resident microcode or firmware that can be updated in the field has a separate Test unit for both the display of the installed microcode or firmware level and the installation of the microcode or firmware. Use a separate Test Unit for each specific function (display and install) as follows:

<table>
<thead>
<tr>
<th>Test Unit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microcode Display:</td>
<td>This Test Unit provides the calling application with all the present microcode revision levels residing in the adapter or device under test. All device specific output resulting from a microcode device or adapter queries are passed to the calling application using OUTPUT_DATA (*data_log) as defined in TU_INPUT_TYPE. For more information refer to Definition of EXECTU().</td>
</tr>
<tr>
<td>Microcode Installation:</td>
<td>This Test Unit provides a function to update the Adapter or Device Microcode. The Microcode file name is passed from the calling application using INPUT_DATA (*tu_data) as defined in TU_INPUT_TYPE. For more information refer to Definition of EXECTU().</td>
</tr>
</tbody>
</table>

Enhanced Error Handling Option
The Diagnostics Test Units Application interface consists of adapting all read functions as follows:

- All data reads for the adapter must be verified that the data read is other than all 1s, unless otherwise expected. Any data reads that result in all 1s produce a unique error, which is reported to the Diagnostics application.
- A test unit that expects all 1s as normal operation, because of a particular test's nature, does not report the error until that error is verified by the requesting data as being caused by all 1s.
- Diagnostics application developers and test unit developers must determine jointly a unique error code for enhanced error handling.

Diagnostic Kernel Extension
This section describes the use of and programming interfaces to the Diagnostic Kernel Extension (PDIAGEX) and device configuration services. The pdiag_ calls are contained in /usr/lib/libpdiag.a. The pdiag_dd_ calls are contained in /usr/lib/drivers/pdiagex kernel extension.

The following topics are discussed in detail:
- Overview
- Device Configuration
- Loading PDIAGEX
- Second-Level Interrupt Handlers
- Programming Interfaces for libpdiag.a
• Programming Interfaces for PDIAGEX
• Data Dictionary

Overview
The Portable Diagnostic Kernel Extension (PDIAGEX) is designed to allow a user-level application to exercise or test a device without requiring specialized diagnostic code to be added to the device driver. PDIAGEX is loaded and bound into the kernel by the Diagnostic Controller before the application is invoked.

PDIAGEX provides system calls for reading and writing device registers, performing Direct Memory Access (DMA), and handling interrupts.

To use PDIAGEX for exercising a device, make the device unavailable to the rest of the system by invoking device methods to move the device from the DEFINED or AVAILABLE state to the DIAGNOSE state. Once the device is in the DIAGNOSE state, the device may be exercised using PDIAGEX. This is accomplished by using the libpdiag.a call pdiag_diagnose_state.

Applications using PDIAGEX must be linked with the pdiagex.exp file specified as an import file.

Device Configuration
Using PDIAGEX requires that serialization be used to limit access to the adapters by the diagnostics and the normal device drivers. Serialization is provided by the device configuration software.

A device state, DIAGNOSE, is defined. The state is identified by state=4 in the CuDv object for the device. A define statement:
#define DIAGNOSE 4

has been added to the /usr/include/sys/cfgdb.h file.

This state can be entered only from the DEFINED state and only by running the /usr/lib/methods/cfgdiag method. From the DIAGNOSE state, a device can be changed back to the DEFINED state only by running the /usr/lib/methods/ucfgdiag method. Transitions between the AVAILABLE and DIAGNOSE states are not allowed. This provides a mechanism for serializing access to the devices that support this DIAGNOSE state. While in the AVAILABLE state, a device’s normal device driver is loaded and operational, but while it is in the DIAGNOSE state, the PDIAGEX (or separate diagnostic device driver) is loaded and has control of the device.

The /usr/lib/methods/cfgdiag method checks that the parent of the device is in the correct state. If the device is a Micro Channel® adapter, it verifies that the adapter is in the slot. Busresolve then runs to ensure that bus resources are allocated properly.

Two diagnostic library routines have been created to move the device and its children to their appropriate states for testing. The routines are pdiag_diagnose_state and pdiag_restore_state.

Loading PDIAGEX
The Diagnostic Controller coordinates the loading and unloading of the kernel extensions required before executing the Diagnostic Application. The KernExt field in the PDiagRes and PDiagTask object class is used to tell the Controller that the device requires a kernel extension. This is a ‘,’ comma-separated list of required kernel extensions for the application. Each kernel extension is loaded before the application is invoked.
Second-Level Interrupt Handlers
All second-level interrupt handlers should reside in the directory /usr/lpp/diagnostics/slih. This directory is defined by environment variable DIAGX_SLIH_DIR. Avoid code names at all times. Use the component name if applicable.

Programming Interfaces for libpdiag.a

pdiag_diagnose_state

**Purpose**
Puts the device under test into the correct state for testing.

**Syntax**
```
#include <sys/pdiag_def.h>

int32   pdiag_diagnose_state ( char *device_instance )
```

**Description**
The pdiag_diagnose_state subroutine unconfigures the device, and its children if necessary, to set the device into the DIAGNOSE state. Original states of all devices changed will be saved. Use pdiag_restore_state to put the changed devices back to their original states.

This function is platform-implementation specific. Its main purpose is to make sure that the target device is in the correct state for diagnostic purposes and that the Enhanced Error Handling (EEH) option is enabled during the test. If the device is already in a diagnostic state, or any state allowed by the operating system for this purpose, then this function should return a successful status value of zero. If an error occurs, then this function should return a non-zero value.

The global variable diag_cfg_errno will be set to the return value of the method invoked for the device.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>device_instance</td>
<td>Name of the device under test.</td>
</tr>
</tbody>
</table>
Return Value
The `pdiag_diagnose_state` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful return.</td>
</tr>
<tr>
<td>-1</td>
<td>Software error. Error returned from device method. The <code>diag_cfg_errno</code> variable contains the error code from the device method. Refer to the <code>/usr/include/cf.h</code> file. The <code>E_FINDCHILD</code> and <code>E_NEWCHILD</code> values are not failures. EEH hardware error.</td>
</tr>
<tr>
<td>1</td>
<td>Error returned from device method. The <code>diag_cfg_errno</code> variable contains the error code from the device method. Refer to the <code>/usr/include/cf.h</code> file. The <code>E_FINDCHILD</code> and <code>E_NEWCHILD</code> values are not failures.</td>
</tr>
</tbody>
</table>

Related Information
The `pdiag_diagnose_multifunc_state`, `pdiag_restore_state`, and `pdiag_restore_multifunc_state` subroutines.

`pdiag_diagnose_multifunc_state`

Purpose
Puts a single function device, a multifunction non-bridged device, and a bridged device under test, into the correct state for testing.

Syntax
```c
#include <sys/pdiag_def.h>
int32 pdiag_diagnose_multifunc_state (char *device_instance, int eeh_activate)
```

Description
The `pdiag_diagnose_multifunc_state` subroutine unconfigures the device, and its children if necessary, to set the device into the DIAGNOSE state. The original states of all changed devices will be saved. Use `pdiag_restore_multifunc_state` to put the changed devices back to their original states.

This function is platform-implementation specific. Its main purpose is to make sure that the target device is in the correct state for diagnostic purposes, and that the Enhanced Error Handling (EEH) option is enabled during test. If the device is already in a diagnostic state, or any state allowed by the operating system for this purpose, this function should return successful status. If an error occurs, this function should return a non-zero.

The global variable, `diag_cfg_errno`, will be set to the return value of the method invoked for the device.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>device_instance</code></td>
<td>Name of device under test.</td>
</tr>
</tbody>
</table>
| `eeh_activate` | 0 Do not enable the EEH option  
 1 Enable the EEH option for bridged adapters  
 2 Enable the EEH option for multifunction non-bridged adapters  
 3 Enable the EEH option for single function adapters |

Return Value
The `pdiag_diagnose_multifunc_state` subroutine function returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful return</td>
</tr>
<tr>
<td>-1</td>
<td>Software error</td>
</tr>
</tbody>
</table>
Return Value | Description
---|---
1 | Error returned from device method. The diag_cfg_errno variable contains the error code from the device method. Refer to the /usr/include/cf.h file. The E_FINDCHILD and E_NEWCHILD values are not failures.
-2 | Hardware error

Related Information

The `pdiag_diagnose_state`, `pdiag_restore_state`, and `pdiag_restore_multifunc_state` subroutines.

pdiag_restore_state

Purpose

Restores resource and children to their initial state before testing.

Syntax

```c
#include <sys/pdiag_def.h>

int32 pdiag_restore_state ( char *device_instance )
```

Description

The `pdiag_restore_state` subroutine puts the device, and its children if necessary, back to the original state before the `pdiag_diagnose_state` routine was called.

This function is platform-implementation specific. Its main purpose is to make sure that the target device is back in its original state prior to performing diagnostics on the device, and that the Enhanced Error Handling (EEH) option is disabled. If the device is already in the correct state, then this function should return a successful status value of zero. If an error occurs, then this function should return a non-zero value.

The `diag_cfg_errno` global variable will be set to the return value of the method invoked for the device.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>device_instance</code></td>
<td>Name of the device under test.</td>
</tr>
</tbody>
</table>

Return Value

The `pdiag_restore_state` subroutine returns one of the following values:

| Return Value | Description
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful return.</td>
</tr>
<tr>
<td>-1</td>
<td>Software error.</td>
</tr>
<tr>
<td>1</td>
<td>Error returned from device method. The <code>diag_cfg_errno</code> variable contains the error code from the device method. Refer to the /usr/include/cf.h file. The E_FINDCHILD and E_NEWCHILD values are not failures.</td>
</tr>
<tr>
<td>-2</td>
<td>EEH hardware error.</td>
</tr>
</tbody>
</table>

Related Information

The `pdiag_diagnose_state`, `pdiag_diagnose_multifunc_state`, and `pdiag_restore_multifunc_state` subroutines.

pdiag_restore_multifunc_state

Purpose

Restores a device and its children to their initial state before testing.

72  AIX Version 6.1 Understanding the Diagnostic Subsystem for AIX
Syntax
#include <sys/pdiag_def.h>
int32 pdiag_restore_multifunc_state (char *device_instance, int eeh_activate)

Description
The `pdiag_restore_multifunc_state` subroutine puts the device, and its children if necessary, back to the original state before the `pdiag_diagnose_multifunc_state` routine was called.

This function is platform-implementation specific. Its main purpose is to make sure that the target device is back in its original state before diagnostic functions were performed on the device and the Enhanced Error handling (EEH) option is returned to the state originally encountered. If the device is already in the correct state, this function should return a successful status. If an error occurs, this function should return a non-zero.

The `diag_cfg_errno` global variable will be set to the return value of the method invoked for the device.

Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>device_instance</td>
<td>Name of device under test.</td>
</tr>
<tr>
<td>eeh_activate</td>
<td>0       Do not disable the EEH option</td>
</tr>
<tr>
<td></td>
<td>1       Disable the EEH option</td>
</tr>
</tbody>
</table>

Return Value
The `pdiag_restore_multifunc_state` function returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful return</td>
</tr>
<tr>
<td>-1</td>
<td>Software error</td>
</tr>
<tr>
<td>1</td>
<td>Error returned from device method. The <code>diag_cfg_errno</code> variable contains the error code from the device method. Refer to the <code>/usr/include/cf.h</code> file. The <code>E_FINDCHILD</code> and <code>E_NEWCHILD</code> values are not failures.</td>
</tr>
<tr>

<td>Hardware error</td>
</tr>
</tbody>
</table>

Related Information
The `pdiag_restore_state`, `pdiag_diagnose_state`, and `pdiag_diagnose_multifunc_state` subroutines.

`pdiag_cs_open`

Purpose
Opens and initializes the configuration services, which are used to obtain device information. This is the Object Data Manager (ODM).

Syntax
`int32 pdiag_cs_open ( )`

Description
The `pdiag_cs_open` subroutine issues an `odm_initialize` call to the Object Data Manager.

Parameters
Takes no parameters.

Return Value
A value of 0 is always returned.
pdiag_cs_close

Purpose
Closes the configuration services, which are used to obtain device information. This is the Object Data Manager (ODM).

Syntax
```c
int32 pdiag_cs_close ( )
```

Description
The `pdiag_cs_close` subroutine issues an `odm_terminate` call to the Object Data Manager.

Parameters
Takes no parameters.

Return Value
A value of 0 is always returned.

pdiag_cs_get_attr

Purpose
Returns resource attribute information.

Syntax
```c
int32 pdiag_cs_get_attr ( char *device_instance, char *attribute,
                          char **cvalue, char *type )
```

Description
The `pdiag_cs_get_attr` subroutine searches the data configuration database to obtain the value of the attribute for the device. The value and type is returned to the calling application.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>device_instance</td>
<td>Name of the device under test.</td>
</tr>
<tr>
<td>attribute</td>
<td>Character string describing attribute to be retrieved. Supported device attribute names: alias, all_addr, attrn_mac, beacon_mac, bus_addr_start, bus_id, bus_intr_lvl, bus_io_addr, bus_io_length, bus_mem_addr, bus_mem_start, bus_type, dma1_start, dma2_start, dma3_start, dma4_start, dma_bus_mem, dma_channel, dma_lvl, gd_frequency</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>

<tr>
<td>vram_start</td>
<td></td>
</tr>
<tr>
<td>xmt_que_size</td>
<td></td>
</tr>
</tbody>
</table>

$cvalue$ Pointer to data buffer, set by this function to address of buffer allocated to hold the attribute data.

$type$ Character set by this function to indicate the returned data type. Supported data types are:

- $s$ String
- $i$ Long integer

### Return Value
A value of 0 is returned if successful.

### `pdiag_cs_free_attr`

**Purpose**
Frees a buffer allocated by a `pdiag_cs_get_attr` request.

**Syntax**
```c
int32 pdiag_cs_free_attr ( char *cvalue )
```

**Description**
The `pdiag_cs_free_attr` subroutine frees the buffer allocated by a previous `pdiag_cs_get_attr` call.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$cvalue$</td>
<td>Pointer to previously allocated data buffer.</td>
</tr>
</tbody>
</table>

**Return Value**
A value of 0 is returned if successful.

### `pdiag_open`

**Purpose**
Prepares a resource for testing.

**Syntax**
```c
#include <sys/pdiagex_dds.h>
#include <sys/pdiag_def.h>

int32 pdiag_open( device_instance, dds_ptr, int_handler, handle )
```

```c
pdiag_addr_t     device_instance;
pdiagex_dds_t   *dds_ptr;
pdiag_addr_t    *int_handler;
pdiag_info_handle_t *handle;
```
Description
The **pdiag_open()** function allocates memory for a handle for this particular resource. The **pdiagex_dds_t** structure contains information about the resource to be tested. The Test Unit code must initialize the data in this structure before calling **pdiag_open**. The returned **pdiag_info_handle_t** structure is the handle created for the resource. The Test Unit does not need to know any of the internal details of this structure, but must retain the pointer for use in subsequent function calls. The DMA channel is initialized by calling the **d_init** kernel service and then the DMA channel is unmasked for transfer; that is, you are not required to do a **pdiag_dd_dma_setup()**. For Micro Channel bus_types, it also initializes a DMA TCW management table to indicate that all buffers are available.

If a user interrupt-handler routine exists, it pins the handler, initializes this handler (using the **i_init** kernel service), and allocates memory for interrupt data.

Both this routine and **pdiag_close()** share a common lock while executing to prevent simultaneous resource allocation/deallocation. If a call is made to this routine or **pdiag_close()** while the lock is being held by a previous call, the calling process will sleep until the routine is available.

**Note:** In some instances, the members of the dds structure may not be necessary. For example, if dds->bus_type is equal to BUS_60X, the dds members, **bus_io_addr**, **bus_io_length**, **dma_bus_addr**, **dma_bus_length**, **dma_lvl**, **dma_flags**, and **dma_chan_id** are not used and are ignored by **PDIAGEX**. See "Programming Interfaces for libpdiag.a" on page 70.

Execution Environment
The **pdiag_open()** function can be called from the process environment only.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>device_instance</em></td>
<td>Pointer to the string name of the specific device to open.</td>
</tr>
<tr>
<td><em>dds_ptr</em></td>
<td>Points to a <strong>pdiagex_dds_t</strong> structure which should already be initialized with attributes for the particular resource described by the dds (see &quot;Data Dictionary&quot;).</td>
</tr>
<tr>
<td><em>int_handler</em></td>
<td>Pointer to the string name of the interrupt handler to be loaded.</td>
</tr>
<tr>
<td><em>handle</em></td>
<td>Returned pointer to diagnostic resource handle.</td>
</tr>
</tbody>
</table>

Return Value
The **pdiag_open** function returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DGX_OK</strong></td>
<td>The operation was successful. The errno is not set.</td>
</tr>
<tr>
<td><strong>DGX_BOUND_FAIL</strong></td>
<td>An input parameter is out of bounds (<strong>dds.dma_bus_len</strong> is not a multiple of PAGESIZE or zero) (Micro Channel bus type only). The errno is not set.</td>
</tr>
<tr>
<td><strong>DGX_BADVAL_FAIL</strong></td>
<td>An input parameter (<strong>dds.bus_type</strong>) is not valid. The errno is not set.</td>
</tr>
<tr>
<td><strong>DGX_INVALID_HANDLE</strong></td>
<td>Specified handle pointer is not valid. The errno is set to the <strong>suword()</strong> return code.</td>
</tr>
<tr>
<td><strong>DGX_COPYDDS_FAIL</strong></td>
<td>Application could not copy the dds information. The errno is set to the <strong>copyin()/copyout()</strong> return code.</td>
</tr>
<tr>
<td><strong>DGX_DINIT_FAIL</strong></td>
<td>Application could not initialize the DMA channel. The errno is set to the <strong>d_init()</strong> return code.</td>
</tr>
<tr>
<td><strong>DGX_IINIT_FAIL</strong></td>
<td>Application could not initialize the user’s interrupt handler. The errno is set to the <strong>i_init()</strong> return code.</td>
</tr>
<tr>
<td><strong>DGX_KMOD_FAIL</strong></td>
<td>Application could not locate the user’s interrupt handler in kernel space. The errno is set to the <strong>kmod_entrypt()</strong> return code.</td>
</tr>
<tr>
<td><strong>DGX_PINCODE_FAIL</strong></td>
<td>Application could not pin the user’s interrupt handler or the interrupt environment <strong>PDIAGEX</strong> functions. The errno is set to the <strong>pincode()</strong> return code.</td>
</tr>
</tbody>
</table>
Return Value | Description
---|---
DGX_PINU_FAIL | Application could not pin the specified user buffer. The errno is set to the `pinu()` return code.
DGX_XMALLOCFAIL | Application could not allocate resources. The errno is set to the `xmalloc()` return code.
DGX_XMATTACH_FAIL | Application could not attach user buffer to the physical address. The errno is set to the `xmattach()` return code.

Related Information

pdiag_close() function.

pdiag_close

Purpose
Frees up PDIAGEX Kernel Extension resources.

Syntax
```c
#include <sys/pdiagex_dds.h>
#include <sys/pdiag_def.h>

int pdiag_close( handle )
pdiag_info_handle_t handle;
```

Description
The `pdiag_close()` function frees the DMA and interrupt channels, if they were initialized. This function also masks the DMA channel; that is, you are not required to do a `pdiag_dd_dma_complete()` call. Any memory that was allocated, pinned, or cross-memory attached is detached, unpinned, and freed appropriately.

If this is the last use of the user’s interrupt-handler routine, it is unloaded from kernel memory.

Both this routine and `pdiag_open()` share a common lock while executing to prevent simultaneous resource allocation and deallocation. If a call is made to this routine or `pdiag_open()` while the lock is being held by a previous call, the calling process will sleep until the routine is available.

Note: All `pdiag_dd_dma_setup()` calls should be matched with a `pdiag_dd_dma_complete()` call prior to calling this routine. Any outstanding DMA operations results in the failure of this routine.

Execution Environment
The `pdiag_close()` function can be called from the process environment only.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| handle | Pointer to `pdiag_info_handle_t` structure which is returned from `pdiag_open()`.

Return Value
The `pdiag_close` function returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
</table>
| DGX_OK | The operation was successful. The errno is not set. Specified handle has been closed or was not generated by the `(pdiag_open)` call. The errno is not set. An outstanding DMA operation is preventing closure. The errno is not set.
**Related Information**

The **pdiag_open** subroutine.

### pdiag_pcicfg_read

**Purpose**
Reads a PCI Configuration register.

**Syntax**
```c
#include <sys/pdiagex_dds.h>
#include <sys/pdiag_def.h>

int32 pdiag_pcicfg_read( device_instance, reg_offset, datasize, data )
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>device_instance</td>
<td>Pointer to the string name of the specific device to read.</td>
</tr>
<tr>
<td>reg_offset</td>
<td>Contains the offset within the PCI configuration table register to be read.</td>
</tr>
<tr>
<td>datasize</td>
<td>The data size will be specified as follows:</td>
</tr>
<tr>
<td>data</td>
<td>Pointer to the data to be read within the PCI Configuration Table.</td>
</tr>
</tbody>
</table>

**Description**
The **pdiag_pcicfg_read**() function reads 8, 16, or 32 bits of a PCI Configuration register for this particular resource. The **reg_offset** parameter contains the register offset into the device's PCI configuration table. The calling application must provide a valid register offset before calling **pdiag_pcicfg_read**. The returned **data** is the 8, 16, or 32 bit value read from the PCI register configuration table. All the byte swapping required is performed internally by this function; the calling application must not alter the byte positioning of the data.

**Execution Environment**
The **pdiag_pcicfg_read**() function can be called from the process environment only.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>device_instance</td>
<td>Pointer to the string name of the specific device to read.</td>
</tr>
<tr>
<td>reg_offset</td>
<td>Contains the offset within the PCI configuration table register to be read.</td>
</tr>
<tr>
<td>datasize</td>
<td>The data size will be specified as follows:</td>
</tr>
<tr>
<td>data</td>
<td>Pointer to the data to be read within the PCI Configuration Table.</td>
</tr>
</tbody>
</table>

**Note:** The value read is the specified size on the datasize parameter.

**Return Value**
The **pdiag_pcicfg_read** function returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful return</td>
</tr>
<tr>
<td>-1</td>
<td>Software error</td>
</tr>
</tbody>
</table>

**Related Information**
The **pdiag_pcicfg_write**() function.
pdiag_pcicfg_write

Purpose
Writes to a PCI Configuration register.

Syntax
#include <sys/pdiagex_dds.h>
#include <sys/pdiag_def.h>

int32 pdiag_pcicfg_write( device_instance, reg_offset, datasize, data )

pdiag_addr_t device_instance;
ulong reg_offset;
int datasize;
uchar data;

Description
The pdiag_pcicfg_write() function writes 8, 16, or 32 bits to a PCI Configuration register for this particular resource. The reg_offset parameter contains the register offset into the device’s PCI configuration table. The Test Unit code must provide a valid register offset when calling pdiag_pcicfg_write. The data value is the 8, 16, or 32 bit value to be written to the PCI register configuration table depending on the data size specified in the datasize parameter. All the byte swapping required is performed internally by this function; the calling application must not alter the byte positioning of the data.

Execution Environment
The pdiag_pcicfg_write() function can be called from the process environment only.

Parameters
Parameter Description

device_instance Pointer to the string name of the specific device to write.

reg_offset Contains the offset within the PCI configuration table register to be written.

datasize The data size will be specified as follows:

Size Type
8 bits IOCHAR8
16 bits IOSHORT16
32 bits IOLONG32

data Contains the value to be written to a specific PCI register.

Note: The size of the value must be specified in the datasize parameter and must be IOCHAR8, IOSHORT16, or IOLONG32.

Return Value
The pdiag_pcicfg_write function returns one of the following values:

Return Value Description
0 Successful return
-1 Software error

Related Information

Programming Interfaces for PDIAGEX
This section provides information on application programming interfaces to the Portable Diagnostic Kernel Extension PDIAGEX.
Test unit developers should use these interfaces to ensure their code has maximum portability across platforms.

- `pdiag_dd_watch_for_interrupt`
- `pdiag_dd_kick_hdw_and_watch_for_interrupts_safe_mode`
- `pdiag_dd_interrupt_notify`
- `pdiag_dd_write`
- `pdiag_dd_read`
- `pdiag_dd_dma_setup`
- `pdiag_dd_dma_complete`
- `pdiag_dd_dma_enable`
- `pdiag_dd_big_dma_setup`
- `pdiag_dd_big_dma_complete`

**pdiag_dd_big_dma_complete**

*Purpose:* The `pdiag_dd_big_dma_complete()` function unmaps, unpins, and detaches the user space DMA buffer.

*Syntax:*

```c
#include <sys/pdiagex_dds.h>
int32 pdiag_dd_big_dma_complete( handle, daddr, operation )

pdiag_info_handle_t handle;
pdiag_addr_t daddr;
uint32 operation;
```

*Description:*

**Attention:**

- At this time, you can only use this call if the bus type is BUS_BID.
- The operation argument to this function must be `PDIAG_DMA_MASTER`.

The `pdiag_dd_big_dma_complete()` must be called after I/O completion involving the area mapped by the prior `pdiag_dd_big_dma_setup()` function call.

This function utilizes the `D_UNMAP_LIST` macro to unmap the specified address.

*Execution Environment:* The `pdiag_dd_big_dma_complete()` function can only be called from the process environment.

*Parameters:*

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>handle</code></td>
<td>Points to <code>pdiag_info_handle_t</code> structure, which is returned from <code>pdiag_open()</code></td>
</tr>
<tr>
<td><code>daddr</code></td>
<td>The bus address that was returned by the previous <code>pdiag_dd_big_dma_setup()</code> routine.</td>
</tr>
<tr>
<td><code>operation</code></td>
<td>Type of operation to perform.</td>
</tr>
</tbody>
</table>

*Note:* At this time, this must be `PDIAG_DMA_MASTER`.

*Return Value:* The `pdiag_dd_dma_complete` function returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DGX_OK</td>
<td>The operation was successful. The errno is not set.</td>
</tr>
<tr>
<td>DGX_INVALID_HANDLE</td>
<td>Specified handle has been closed or was not generated by the <code>pdiag_open()</code> call. The errno is not set.</td>
</tr>
<tr>
<td>DGX_BADVAL_FAIL</td>
<td>The <code>daddr</code> value is not valid. The errno is not set.</td>
</tr>
</tbody>
</table>
Return Value | Description
--- | ---
DGX_UNPINU_FAIL | Application could not unpin the specified user buffer. The errno is set to the unpinu() return code.
DGX_XMDETACH_FAIL | Application could not detach user space from the physical address. The errno is set to the xmdetach() return code.

Related Information: The `pdiag_dd_big_dma_setup()` function.

pdiag_dd_big_dma_setup

**Purpose:** The `pdiag_dd_big_dma_setup()` function initializes, pins, and cross-memory attaches a large user buffer for a DMA operation. The size can be up to `DIAG_MULTIPAGESIZE` (currently, this is 0x8000) bytes.

**Syntax:**
```
#include <sys/pdiagex_dds.h>
#include <sys/dma.h>
int32 pdiag_dd_big_dma_setup( handle, dma_flags, baddr, users_daddr, count, minxfer, operation )
pdiag_info_handle_t handle;
int32 dma_flags;
pdiag_addr_t baddr;
pdiag_addr_t users_daddr;
uint32 count;
uint32 minxfer;
uint32 operation;
```

**Description:**

**Attention:**
- This function is not supported for Micro Channel or 60X bus type adapters.
- At this time, you can only use this call if the bus type is `BUS_BID`.
- The operation argument to this function must be `PDIAG_DMA_MASTER`.

The following is performed by the `pdiag_dd_big_dma_setup` function depending on the bus type and `operation`:
- The `pdiag_dd_big_dma_setup()` function cross-memory attaches, pins, and maps the user buffer for DMA access by the device. The function currently allows for a transfer sizes greater than 0x1000 bytes, up to `DIAG_MULTIPAGESIZE` (which is 0x8000 bytes). The resulting bus addresses are mapped as a contiguous space.
- This function issues the `d_map_list` kernel call for the specified address. The DMA space is managed for the user.

The following are requirements that must be met in order to use the `pdiag_dd_big_dma_setup()` function:
- The device-dependent structure (DDS) member `maxmaster`, which was previously set with `pdiag_open`(), must have been set to the maximum number of concurrent `pdiag_dd_dma_setup()`s and `pdiag_dd_big_dma_setup()`s to be used (that is, the maximum number of `pdiag_dd_dma_setup()`s and `pdiag_dd_big_dma_setup()`s called above the number of associated `pdiag_dd_dma_complete()`s and `pdiag_dd_big_dma_complete()`s at any given time). `maxmaster` must be set to at least 1 (one) for this call to pass without a `DGX_BOUND_FAIL` error.
- The `DMA_CONTIGUOUS` flag must have been set on the DDS member `dma_flags`, which was previously set with `pdiag_open()`). This function returns only a single bus address as a result of the memory mapping operation. The `DMA_CONTIGUOUS` flag is used to request that the mapping returns only a single address space, rather than a list of discontiguous bus memory regions.
**Execution Environment:** The `diag_dd_big_dma_setup()` function can be called from the process environment only.

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>Points to <code>pdiag_info_handle_t</code> structure, which is returned from <code>pdiag_open()</code>.</td>
</tr>
<tr>
<td>dma_flags</td>
<td>Use the DMA_READ flag for transferring data from the adapter to user memory. Use 0 (zero) for transferring data from the system to the adapter. For more information on other DMA flags, see the <code>sys/dma.h</code> header file.</td>
</tr>
<tr>
<td>baddr</td>
<td>Points to the user’s read or write buffer where the DMA transfer should take place.</td>
</tr>
<tr>
<td>users_daddr</td>
<td>Points to an integer to be filled with the bus memory address of <code>baddr</code> upon successful completion of this call.</td>
</tr>
<tr>
<td>count</td>
<td>Number of bytes to be transferred.</td>
</tr>
</tbody>
</table>

**Return Value:** The `pdiag_dd_big_dma_setup` function returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DGX_OK</td>
<td>The operation was successful. The errno is not set.</td>
</tr>
<tr>
<td>DGX_INVALID_HANDLE</td>
<td>Specified handle has been closed or was not generated by the <code>pdiag_open()</code> call. The errno is not set.</td>
</tr>
<tr>
<td>DGX_BOUND_FAIL</td>
<td>The application tried to set up a DMA outside its resources, the count is too large, the resources are currently unavailable, or <code>maxmaster</code> is set to zero. The errno is not set.</td>
</tr>
<tr>
<td>DGX_BADVAL_FAIL</td>
<td>PDIAGEX was unable to update the specified <code>daddr</code>. This might be because the DMA_CONTIGUOUS flag was not set as described above, or other causes. The errno is set to the <code>suword()</code> return code.</td>
</tr>
<tr>
<td>DGX_PINU_FAIL</td>
<td>The application could not pin the specified user buffer. The errno is set to the <code>pinu()</code> return code.</td>
</tr>
<tr>
<td>DGX_XMATTACH_FAIL</td>
<td>The application could not attach user buffer to the physical address. The errno is set to the <code>xmattach()</code> return code.</td>
</tr>
<tr>
<td>DGX_XMALLOC_FAIL</td>
<td>The function could not allocate necessary temporary memory. The errno is not set.</td>
</tr>
<tr>
<td>DGX_FAIL</td>
<td>The user memory could not be mapped to bus memory space. The errno is set to the return code from the <code>d_map_list()</code> call.</td>
</tr>
</tbody>
</table>

**Related Information:** The `pdiag_dd_big_dma_complete` function.

**pdiag_dd_kick_hdw_and_watch_for_interrupts_safe_mode**

**Purpose:** The `pdiag_dd_kick_hdw_and_watch_for_interrupts_safe_mode()` function writes any number of locations in the hardware and sleeps until a desired number of interrupts occur or a timeout occurs. The timeout occurs if any of the expected interrupts does not occur within the timeout time for that interrupt.

The `pdiag_dd_kick_hdw_and_watch_for_interrupts_safe_mode()` function provides a thread-safe way to kick off a hardware operation and guarantees that all (up to four) expected `pdiag_dd_interrupt_notify()` service calls by the adapter SLIH are not missed by this routine. A pdiagex internal locking mechanism prevents interrupts from being missed. The user SLIH will not be called until this routine first releases the lock.

The legacy routine does not handle the hardware kick-off operation. With the legacy function, the hardware interrupt may have already occurred before the user application calls the legacy watch function.

**Syntax:**
```c
#include <sys/pdiagex.dds.h>

int32 pdiag_dd_kick_hdw_and_watch_for_interrupts_safe_mode(
    handle, kick_vec_parm_p, num_kick_records, num_intrpts_expected, flag_found_p, timeout_sec);

pdiag_info_handle_t handle;
kick_io_t* kick_vec_parm_p;
umt32 num_kick_records;
umt32 num_intrpts_expected;
umt32 *flag_found_p;
umt32 timeout_sec;
```

**Description:** The `pdiag_dd_kick_hdw_and_watch_for_interrupts_safe_mode()` function performs the following operations:

- Copies in the caller-provided table of hardware write operations required to kick off the hardware. This table is an array of `kick_io_t` structures. Each element in the array describes a hardware location that must be written to start the hardware operation. The calling application can pass an array of any size to this routine. The `kick_io_t` structure is described in the `pdiagex.dds.h` header file. The size of the array is passed in using the parameter `num_kick_records`.

- Acquires the pdiagex `intr_lock` lock.
- Clears the `flag_word` variable.
- Kicks off the hardware by writing the addresses, size, and data value or values that were just copied in.
- For each of the interrupts that the user expects (passed in using the `num_intrpts_expected` parameter), this function does an `e_sleep_thread()` system call to process each `pdiag_dd_interrupt_notify()` function that the SLIH generates. The pdiagex `intr_lock` lock is released only during the `e_sleep_thread()` system call. A timeout value for each sleep is passed in using the `timeout_sec` parameter. The `flag_word` variable that the SLIH created is saved for each time the routine is awakened.

- Releases the pdiagex `intr_lock` lock.
- The values of `flag_word` variable saved after each sleep are copied out to the user’s array of type `uint32` variables pointed to by the `flag_found_p` parameter to this routine. The array should be of type `uint32[4]`.

If the SLIH calls `pdiag_dd_interrupt_notify()` function, then the `e_sleep_thread()` system call no longer blocks. Once the SLIH calls `pdiag_dd_interrupt_notify()` function, the kernel guarantees that the `e_sleep_thread()` system call will be first to reacquire the `intr_lock` lock. This means that the SLIH will not be reentered until this routine releases the lock, either starting another `e_sleep_thread()`, or at exit of this routine. The pdiagex and kernel locks only permit the user SLIH to be called once each time this routine does this `e_sleep_thread()` system call.

To be awakened from the sleep state and get interrupt condition information, this routine is highly dependent on the interaction of the application’s interrupt handler. This interaction is maintained by using the `handle.flag_word`, `handle.sleep_word`, and `handle.sleep_flag` variables. The `handle.flag_word` bit format is determined by the user’s application. It must be of type `uint32`.

The application’s interrupt handler should update the `handle.flag_word` each time it receives an interrupt. The application’s interrupt handler should also test the `handle.sleep_flag` each time it receives an interrupt to determine if the `pdiag_dd_watch_for_interrupt()` routine is sleeping. If `handle.sleep_flag` is `TRUE`, the application’s interrupt handler should wake the `pdiag_dd_kick_hdw_and_watch_for_interrupts_safe_mode()` routine using the `pdiag_dd_interrupt_notify()` service with `handle.sleep_word` as the sleep word.

**Execution Environment:** The `pdiag_dd_kick_hdw_and_watch_for_interrupts_safe_mode()` function can be called from the process environment.
**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>Points to <code>pdiag_info_handle_t</code> structure, which is returned from <code>pdiag_open()</code></td>
</tr>
<tr>
<td>kick_vec_param_p</td>
<td>Pointer to a user space array of <code>kick_io_t</code> records. These records are used to describe the hardware write or writes required to initiate an operation that should result in an interrupt caused by the hardware. The <code>kick_io_t</code> is defined in the <code>/usr/include/sys/pdiagex_dds.h</code> header file. It has four uint32 entries that specify the address, data, data type, and whether the register is in I/O space or memory-mapped space.</td>
</tr>
<tr>
<td>num_kick_records</td>
<td>The number of write operations needed to kick off the hardware. This value specifies the number of <code>kick_io_t</code> records that need to be copied from the calling application at the <code>kick_vec_param_p</code> user address.</td>
</tr>
<tr>
<td>num_intrpts_expected</td>
<td>Specifies the number of interrupt notifications that are expected from the SLIH. This must be in the range of 1 to <code>PDIAGEX_MAX_WATCH_INTRPTS</code> interrupts.</td>
</tr>
<tr>
<td>flag_found_p</td>
<td>Pointer to a user space array of <code>PDIAGEX_MAX_WATCH_INTRPTS</code> elements of uint32 type. The routine copies out the values of the <code>flag_word</code> as set by the user’s SLIH, after each sleep.</td>
</tr>
<tr>
<td>timeout_sec</td>
<td>Number of seconds to wait for the interrupt condition before timing out. This value is for each of the <code>num_intrpts_expected</code>. This must always be a non-zero value.</td>
</tr>
</tbody>
</table>

**Return Value:** The `pdiag_dd_kick_hdw_and_watch_for_interrupts_safe_mode()` function returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The operation was successful.</td>
</tr>
<tr>
<td>x80000023</td>
<td>The <code>e_sleep_thread</code> timed out. If any interrupts occurred, the SLIH did not call <code>pdiag_dd_interrupt_notify()</code></td>
</tr>
<tr>
<td>0x80000024</td>
<td>One interrupt notification was received, but the <code>e_sleep_thread</code> timed out the second time. If another interrupt occurred, the SLIH did not call <code>pdiag_dd_interrupt_notify()</code></td>
</tr>
<tr>
<td>0x80000025</td>
<td>Two interrupt notifications were received, but the <code>e_sleep_thread</code> timed out the third time. If another interrupt occurred, the SLIH did not call <code>pdiag_dd_interrupt_notify()</code></td>
</tr>
<tr>
<td>0x80000026</td>
<td>Three interrupt notifications were received, but the <code>e_sleep_thread</code> timed out the fourth time. If another interrupt occurred, the SLIH did not call <code>pdiag_dd_interrupt_notify()</code></td>
</tr>
<tr>
<td>0xFFFFFFFF</td>
<td>The <code>e_sleep_thread</code> failed for reason other than a timeout.</td>
</tr>
<tr>
<td>0x80000000</td>
<td>Specified handle has been closed or was not generated by the <code>pdiag_open()</code> call.</td>
</tr>
<tr>
<td>0x80000027</td>
<td><code>num_intrpts_expected</code> was out of range. It must be 1, 2, 3, or 4.</td>
</tr>
<tr>
<td>0x80000028</td>
<td>The hardware write to kick off the adapter operation failed.</td>
</tr>
</tbody>
</table>

**Related Information:** The `pdiag_dd_dma_enable` and `pdiag_dd_dma_complete` subroutines.

**pdiag_dd_watch_for_interrupt**

**Purpose**

The `pdiag_dd_watch_for_interrupt()` function sleeps until a desired interrupt condition occurs, or a time-out occurs if the interrupt does not occur within the specified time.

**Syntax**

```
#include <sys/pdiagex_dds.h>
int32 pdiag_dd_watch_for_interrupt( handle, flag_mask, timeout_sec )
pdiag_info_handle_t handle;
uint32 flag_mask;
uint32 timeout_sec;
```

**Description**

`pdiag_dd_watch_for_interrupt()` sleeps until a desired interrupt condition occurs or `timeout_sec` seconds pass. If the interrupt condition occurs before the routine is called, the function simply returns, without sleeping. To be awakened from the sleep state and get interrupt condition information, this routine is highly
dependent on the interaction of the application’s interrupt handler. This interaction is maintained by using the \texttt{handle.flag\_word}, \texttt{handle.sleep\_word}, and \texttt{handle.sleep\_flag}.

The application’s interrupt handler should update the \texttt{handle.flag\_word} each time it receives an interrupt. The \texttt{handle.flag\_word} and \texttt{flag\_mask} format is determined by the application. The application’s interrupt handler should also test the \texttt{handle.sleep\_flag} each time it receives an interrupt to determine if the \texttt{pdiag_dd\_watch\_for\_interrupt()} routine is sleeping. If \texttt{handle.sleep\_flag} is TRUE, the application’s interrupt handler should wake the \texttt{pdiag_dd\_watch\_for\_interrupt()} routine using the \texttt{pdiag_dd\_interrupt\_notify()} service with \texttt{handle.sleep\_word} as the sleep word.

**Execution Environment**
The \texttt{pdiag_dd\_watch\_for\_interrupt()} function can be called from the process environment.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{handle}</td>
<td>Points to \texttt{pdiag_info_handle_t} structure which is returned from \texttt{pdiag_open}).</td>
</tr>
<tr>
<td>\texttt{flag_mask}</td>
<td>32-bit flag mask which, when bitwise ANDed with the \texttt{handle.flag_word}, produces a nonzero result only when the \texttt{handle.flag_word} identifies the desired interrupt condition.</td>
</tr>
<tr>
<td>\texttt{timeout_sec}</td>
<td>Number of seconds to watch for the interrupt condition before timing out. (A value of zero will never time-out; possible hang condition).</td>
</tr>
</tbody>
</table>

**Return Value**
The \texttt{pdiag_dd\_watch\_for\_interrupt()} function returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{DGX_OK}</td>
<td>The operation was successful. The errno is not set.</td>
</tr>
<tr>
<td>\texttt{DGX_FAIL}</td>
<td>The interrupt condition did not occur before \texttt{timeout_sec} seconds passed.</td>
</tr>
<tr>
<td>\texttt{DGX_INVALID_HANDLE}</td>
<td>Specified handle has been closed or was not generated by the \texttt{pdiag_open)} call. The errno is not set.</td>
</tr>
</tbody>
</table>

**pdiag_dd\_interrupt\_notify**

**Purpose**
The \texttt{pdiag_dd\_interrupt\_notify()} function can only be used by the interrupt handling function of the TU library. This function notifies a pending \texttt{pdiag_dd\_watch\_for\_interrupt} call that an interrupt has been processed.

**Syntax**

```c
#include <sys/pdiagex_dds.h>
int32 pdiag_dd_interrupt_notify( sleep_word )
uint32 sleep_word;
```

**Description**
The \texttt{pdiag_dd\_interrupt\_notify()} is used to notify a previously pending call to \texttt{pdiag_dd\_watch\_for\_interrupt} that an expected interrupt has been received and processed. This call is only used by the second-level interrupt-handler code provided in the TU library.

**Execution Environment**
The \texttt{pdiag_dd\_interrupt\_notify()} function can only be called from the interrupt environment.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{sleep_word}</td>
<td>Semaphore handle that TU is waiting on, passed in as a parameter to the interrupt handler.</td>
</tr>
</tbody>
</table>
Return Value
The `pdiag_dd_interrupt_notify` function returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DGX_OK</td>
<td>The operation was successful. The errno is not set.</td>
</tr>
</tbody>
</table>

### pdiag_dd_write, pdiag_dd_write_64

**Note:** `pdiag_dd_write_64` is only used in 64-bit kernel.

**Purpose**
The `pdiag_dd_write()` and the `pdiag_dd_write_64()` functions perform write operations on a resource.

**Syntax for 32-Bit Kernel**
```c
#include <sys/pdiagex_dds.h>
int32 pdiag_dd_write( handle, type, offset, data, flags )

pdiag_info_handle_t handle;
uint32 type;
uint32 offset;
pdiag_addr_t data;
pdiagex_opFlags_t *flags;
```

**Syntax for 64-Bit Kernel**
```c
#include <sys/pdiagex_dds.h>
int32 pdiag_dd_write_64( handle, type, offset, data, flags )

pdiag_info_handle_t handle;
uint32 type;
uint32 offset;
pdiag_addr_t data;
pdiagex_opFlags_t *flags;
```

**Description**
The `pdiag_dd_write()` and the `pdiag_dd_write_64()` functions write the specified data to the specified offset address. If the user enables the `times` variable, timing information for this function is also returned. Each write performed is dependent on the `memio` operation and `count` parameters.

<table>
<thead>
<tr>
<th>memio Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PDIAG_IO_OP</td>
<td>If <code>count</code> is 1, data is written to the specified bus I/O offset address.</td>
</tr>
<tr>
<td>PDIAG_MEM_OP</td>
<td>If <code>count</code> is 1, data is written to the specified memory offset address.</td>
</tr>
<tr>
<td>PDIAG_POS_OP</td>
<td>If <code>count</code> is 1, data is written to the specified POS offset address.</td>
</tr>
</tbody>
</table>

A specified number of write accesses to the offset address may be performed if `count` is greater than 1. The user may choose to write the data to one location (the offset address) `count` times, or write the data to `count` consecutive locations, starting at the offset address. In either case, the data to be written is supplied by consecutive locations of the `data` buffer starting at the specified buffer address.

**Note:** When writing data, it is imperative that the write data buffer is at least the size of `count * type` (unless the write data buffer address is not being incremented) and filled with valid data for each write operation to be performed. If this is not done, meaningless data is written to the designated area. This may cause problems with your testing.

**Execution Environment**
The `pdiag_dd_write()` function can be called from the process or the interrupt environment. The `pdiag_dd_write_64()` function can only be called from the interrupt environment.

</tbody>
</table>

intrlev
Indicates which environment the calling routine is in:

**PROCLEV**
If calling from the process level.

**INTRKMEM**
If calling from the interrupt level and the data buffer is in kernel memory.

Note: For the **pdiag_dd_write** function, the intrlev parameter may be set to either PROCLEV or INTRKMEM. For the **pdiag_dd_write_64** function, the intrlev parameter must always be set to INTRKMEM.

| times                          | Points to the timestruc_t structure which returns timing information. If times is a null pointer, no timing information will be returned back to the user. |

**Return Value**
The **pdiag_dd_write** and the **pdiag_dd_write_64** functions return one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DGX_OK</td>
<td>The operation was successful. The errno is not set.</td>
</tr>
<tr>
<td>DGX_INVALID_HANDLE</td>
<td>Specified handle has been closed or was not generated by the pdiag_open() call. The errno is not set.</td>
</tr>
<tr>
<td>DGX_BOUND_FAIL</td>
<td>offset given was larger than the width of the I/O address range. The errno is not set.</td>
</tr>
<tr>
<td>DGX_BADVAL_FAIL</td>
<td>Type field was not valid (that is, not IOCHAR8, IOSHORT16, or IOLONG32). The errno is not set.</td>
</tr>
<tr>
<td>DGX_FAIL</td>
<td>Error occurred during the I/O write access. The errno is set to BUS_PUT(L/S/C)X macro return code.</td>
</tr>
<tr>
<td>DGX_COPY_FAIL</td>
<td>User data buffer could not be copied to or from kernel memory. The errno is set to the xmemin/out or copyin/out return code.</td>
</tr>
</tbody>
</table>

**Related Information**
**pdiag_dd_read, pdiag_dd_read_64** function.

**pdiag_dd_read, pdiag_dd_read_64**

Note: **pdiag_dd_read_64** is only used in the 64-bit kernel.

**Purpose**
The **pdiag_dd_read()** and the **pdiag_dd_read_64()** functions perform read operations on a resource.
Syntax for 32-Bit Kernel
#include <sys/pdiagex.dds.h>
int32 pdiaq_dd_read (handle, type, offset, data, flags )
pdiag info handle_t handle;
uint32 type;
uint32 offset;
pdiag_addr_t data;
pdiagex_opflags_t *flags;

Syntax for 64-Bit Kernel
#include <sys/pdiagex.dds.h>
int32 pdiaq_dd_read_64 ( handle, type, offset, data, flags )
pdiag info handle_t handle;
uint32 type;
uint32 offset;
pdiag_addr_t data;
pdiagex_opflags_t *flags;

Description
The pdiaq_dd_read() and the pdiaq_dd_read_64() functions read the data from the specified address. If
the user enables the times variable, timing information for this function is also returned. Each read
performed is dependent on the memio operation and count parameters.

<table>
<thead>
<tr>
<th>memio Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PDIAG_IO_OP</td>
<td>If count is 1, data is read from the specified bus I/O offset address.</td>
</tr>
<tr>
<td>PDIAG_MEM_OP</td>
<td>If count is 1, data is read from the specified memory offset address.</td>
</tr>
<tr>
<td>PDIAG_POS_OP</td>
<td>If count is 1, data is read from the specified POS offset address.</td>
</tr>
</tbody>
</table>

A specified number of read accesses from the offset address may be performed if count is greater than 1.
The user may choose to read the data from one location (the offset address) count times, or read the data
from count consecutive locations, starting at the offset address. In either case, the read data is stored in
the data buffer starting at the specified buffer address.

Note: When reading data, it is imperative that the read data buffer is at least the size of count * type
(unless the read data buffer address is not being incremented). If this is not done, meaningless data
is written to an area outside the read buffer. This may cause problems with your testing.

Execution Environment
The pdiaq_dd_read() function can be called from the process or the interrupt environment. The
pdiaq_dd_read_64() function can only be called from the interrupt environment.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>Points to pdiag_info_handle_t structure which is returned from [pdiag_open]).</td>
</tr>
</tbody>
</table>
| type      | Defines the data length (byte, word or long) read from the address specified when type is
            IOCHAR8, IOSHORT16, and IOLONG32 respectively. |
| offset    | Offset value that is dependent on the type of operation being performed. It can be one of
            the following values:
            PDIAG_IO_OP
            offset from base I/O address. |
            PDIAG_MEM_OP
            offset from base memory address. |
            PDIAG_POS_OP
            offset from base POS address. |
**Parameter**

**data**
Address of the information read from the specified address.

**Note:** For PDIAG_IO_OP and PDIAG_MEM_OP: The value read from the specified offset will be placed at the specified data address in the form specified by type. If the data buffer is smaller than the specified type, the value will overwrite the bounds of your buffer. If the data buffer is larger than the specified type, the value will reside in the upper type bytes of the buffer.

For PDIAG_POS_OP: The value read from the specified offset will be placed at the specified data address and will occupy 1 byte. If the data buffer is larger than 1 byte, the value will reside in the upper byte of the buffer.

**flags**
The flags structure contains the following members:

- **memio**
  Indication of the type of read operation to perform.
  - PDIAG_IO_OP
    For I/O read operations.
  - PDIAG_MEM_OP
    For memory read operations.
  - PDIAG_POS_OP
    For I/O Configuration Space read operations.

**count**
Number of accesses to perform.

- **PDIAG_IO_OP**
  Number of read operations to be performed.
- **PDIAG_MEM_OP**
  Number of times data is read.
- **PDIAG_POS_OP**
  Count should be set to 1.

**addr_incr_flag**
Determines whether the data buffer address and the offset address get incremented on each of count accesses:

- **PDIAG_SING_LOC_ACC**
  Single-location accesses: neither address is incremented.
- **PDIAG_SING_LOC_BUF**
  Single-location access for buffer: the data address is never incremented. The address referred to by offset is incremented by type.
- **PDIAG_SING_LOC_HW**
  Single-location access for hardware: the data address is incremented by type. The address referred to by offset is not incremented.
- **PDIAG_MULT_LOC_ACC**
  Multiple-location accesses: both addresses are incremented by type.

**intrlev**
Indicates which environment the calling routine is in:

- **PROCLEV**
  If calling from the process level
- **INTRKMEM**
  If calling from the interrupt level and the data buffer is in kernel memory.

**times**
Points to the timestruc_t structure which returns timing information. If times is a null pointer, no timing information will be returned back to the user.
Return Value
The **pdiag_dd_read** and the **pdiag_dd_read_64** functions return one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DGX_OK</td>
<td>The operation was successful. The errno is not set.</td>
</tr>
<tr>
<td>DGX_INVALID_HANDLE</td>
<td>Specified handle has been closed or was not generated by the <strong>pdiag_open</strong> call. The errno is not set.</td>
</tr>
<tr>
<td>DGX_BOUND_FAIL</td>
<td>Offset given was larger than the width of the I/O address range. The errno is not set.</td>
</tr>
<tr>
<td>DGX_BADVAL_FAIL</td>
<td>Type field was not valid (that is, not IOCHAR, IOSHORT, or IOLONG). The errno is not set.</td>
</tr>
<tr>
<td>DGX_FAIL</td>
<td>Error occurred during the I/O read access. The errno is set to BUS_GET(L/S/C)X macro return code.</td>
</tr>
<tr>
<td>DGX_COPY_FAIL</td>
<td>User data buffer could not be copied to or from kernel memory. The errno is set to the xmemin/out or copyin/out return code.</td>
</tr>
</tbody>
</table>

Related Information
**pdiag_dd_write, pdiag_dd_write_64** function.

**pdiag_dd_dma_setup**

**Purpose**
The **pdiag_dd_dma_setup**() function initializes, pins, and cross-memory attaches the user buffer for a DMA operation.

**Syntax**
```c
#include <sys/pdiagex_dds.h>
#include <sys/dma.h>
int32 pdiag_dd_dma_setup( handle, dma_flags, baddr, users_daddr, count, minxfer,operation )
```

**Description**
The following is performed by the **pdiag_dd_dma_setup** depending on the bus type and **operation**:

Where bus type = BUS_MICRO_CHANNEL or BUS_60X and operation is PDIAG_DMA_MASTER
- The DMA master function on Micro Channel and 60X bus systems pins and cross-memory attaches the user buffer for the length of **count**.

  For Micro Channel bus type adapters, the DMA master function issues the **d_master** kernel call for the specified address and length. The DMA address space is managed for you, and the offset into the DMA buffer is supplied in the **daddr** parameter. For 60X bus type adapters, the DMA master function issues the **xmemdma** kernel call for each page referred to by the specified address and length. The flags for this call will be (XMEM_HIDE | XMEM_ACC_CHK). The DMA address space is not managed for you, and the offset into the DMA buffer is supplied in the **daddr** parameter.

  **Note:** The **dds** member, maxmaster, must be set to the maximum number of concurrent **pdiag_dd_dma_setup()**s to be used (that is, maximum number of **pdiag_dd_dma_setup()**s called above the number of associated **pdiag_dd_dma_complete()**s at any given time). **maxmaster** must be set to at least 1 (one) for this call to pass without a DGX_BOUND_FAIL error.
Where bus type = BUS_BID and operation is PDIAG_DMA_MASTER

- The `pdiag_dd_dma_setup()` function pins and cross-memory attaches the user buffer. The function allows for a transfer of 4k or 1 page. The transfer cannot cross a page boundary. Larger transfers are not allowed at this time.

This function issues the `d_map_page` kernel call for the specified address. The DMA space is managed for the user, and the offset into the DMA buffer is supplied in the `users_daddr` parameter.

Where bus type = BUS_MICRO_CHANNEL and operation is PDIAG_DMA_SLAVE

- For slave operation on a Micro Channel, the `pdiag_dd_dma_setup()` function issues the `d_slave` kernel call for the specified length. Only one Micro Channel slave DMA may occur at a time.

**Note:** The `dds` member, `maxmaster`, must be set to at least 1 (one) for this call to pass without a DGX_BOUND_FAIL error.

### Execution Environment

The `pdiag_dd_dma_setup()` function can be called from the process environment only.

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>Points to <code>pdiag_info_handle_t</code> structure which is returned from <code>pdiag_open()</code></td>
</tr>
<tr>
<td>dma_flags</td>
<td>This flag is ignored for 60X bus type adapters. The following refers only to Micro Channel bus type adapters.</td>
</tr>
</tbody>
</table>

Use the DMA_READ flag for transferring data from the adapter to user memory. Use 0 (zero) for transferring data from the system to the adapter. See the header file `sys/dma.h` for more information on other DMA flags.

If the user wants to read or modify data before calling `pdiag_dd_dma_complete()`, then DMA_NOHIDE should also be set. This may be useful for devices that set up long-term DMA mapping for purposes of communication (such as command blocks, status blocks, common buffer pools). Then the `pdiag_dd_dma_complete()` does not have to be called each time they want to let the application read/write, and then `pdiag_dd_dma_setup()` again for the next DMA transfer.

If DMA_NOHIDE is set and the user wants to read data before calling `pdiag_dd_dma_complete()`, then call the `pdiag_dd_dma_enable()` routine to flush and read the data. If DMA_NOHIDE is set and the user wants to write data before calling `pdiag_dd_dma_complete()`, then after the user modifies the data, call the `pdiag_dd_dma_enable()` routine with a flush operation. Make sure that the adapter will not be transferring data to the same area that the user is manipulating.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>baddr</td>
<td>Points to user’s read or write buffer where DMA transfer should take place.</td>
</tr>
<tr>
<td>users_daddr</td>
<td>Points to an integer to be filled with the physical memory address of <code>baddr</code> upon successful completion of this call.</td>
</tr>
<tr>
<td>count</td>
<td>Number of bytes to be transferred.</td>
</tr>
<tr>
<td>minxfer</td>
<td>Minimum transfer length that the device will handle. (Slave transfer only on BUS_BID).</td>
</tr>
<tr>

</thead>
<tbody>
<tr>
<td><code>DGX_INVALID_HANDLE</code> Specified handle has been closed or was not generated by the <code>pdiag_open()</code> call. The <code>errno</code> is not set.</td>
</tr>
<tr>
<td><code>DGX_BOUND_FAIL</code> Application tried to setup a DMA outside its resources, the resources are currently unavailable, or the <code>dds</code> member <code>dma_bus_length</code> (Micro Channel only) or <code>maxmaster</code> is set to zero. The <code>errno</code> is not set.</td>
</tr>
<tr>
<td><code>DGX_BADVAL_FAIL</code> <code>PDIAGEX</code> was unable to update the specified <code>daddr</code>. The <code>errno</code> is set to the <code>suword()</code> return code.</td>
</tr>
<tr>
<td><code>DGX_PINU_FAIL</code> Application could not pin the specified user buffer. The <code>errno</code> is set to the <code>pinu()</code> return code.</td>
</tr>
<tr>
<td><code>DGX_XMATTACH_FAIL</code> Application could not attach user buffer to the physical address. The <code>errno</code> is set to the <code>xmattach()</code> return code.</td>
</tr>
</tbody>
</table>

### Related Information

The `pdiag_dd_dma_enable` and `pdiag_dd_dma_complete` subroutines.

#### pdiag_dd_dma_complete

### Purpose

The `pdiag_dd_dma_complete()` function unpins and detaches the user space DMA buffer. If the handle’s `dds.bus_type` is set for the Micro Channel, this function also calls the `d_complete()` kernel service, which checks for detected IOCC errors, flushes the IOCC buffer (unhides it if necessary) and sets the page table ‘modified’ bit if the information was modified.

### Syntax

```c
#include <sys/pdiagex_dds.h>
int32 pdiag_dd_dma_complete( handle, daddr, operation )

pdiag_info_handle_t handle;
pdiag_addr_t daddr;
uint32 operation;
```

### Description

The following is performed by the `pdiag_dd_dma_complete` depending on the bus type and `operation`:

Where bus type = BUS_MICRO_CHANNEL and operation is PDIAG_DMA_MASTER or PDIAG_DMA_SLAVE

- **The `pdiag_dd_dma_complete()` function cleans up after the DMA transfer. First, the specified `daddr` is used to retrieve the `baddr`, `count`, and `dma_flags` specified in the corresponding `pdiag_dd_dma_setup()` calls. `pdiag_dd_dma_complete()` then issues the `d_complete` kernel call using these parameters. The user address space used for the DMA transfer is then unpinned, detached, and made available for another DMA transfer.**

Where bus type = BUS_BID and operation is PDIAG_DMA_MASTER

- **The `pdiag_dd_dma_complete()` should be called after I/O completion involving the area mapped by the prior `pdiag_dd_dma_setup()` function call. This function utilizes the `D_UNMAP_PAGE` macro to unmap the specified address.**

Where bus type = BUS_BID and operation is PDIAG_DMA_SLAVE

- **The `pdiag_dd_dma_complete()` should be called after I/O completion involving the area mapped by the prior `pdiag_dd_dma_setup()` function call. This function utilizes the `D_UNMAP_SLAVE` macro to unmap the specified address.**

### Execution Environment

The `pdiag_dd_dma_complete()` function can be called from the process or the interrupt environment on a BUS_MICRO_CHANNEL system. The function can only be called from the process environment on a BUS_BID system.
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>Points to <code>pdiag_info_handle_t</code> structure which is returned from <code>pdiag_open()</code> function.</td>
</tr>
<tr>
<td>daddr</td>
<td>The offset into the user’s physical DMA address. This is returned by <code>pdiag_dd_dma_setup()</code> routine. For DMA slave completes, this should be set to 0.</td>
</tr>
<tr>
<td>operation</td>
<td>Type of operation to perform:</td>
</tr>
<tr>
<td></td>
<td>PDIAG_DMA_MASTER</td>
</tr>
<tr>
<td></td>
<td>PDIAG_DMA_SLAVE</td>
</tr>
</tbody>
</table>

Return Value

The `pdiag_dd_dma_complete` function returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DGX_OK</td>
<td>The operation was successful. The errno is not set.</td>
</tr>
<tr>
<td>DGX_INVALID_HANDLE</td>
<td>Specified handle has been closed or was not generated by the <code>pdiag_open()</code> call. The errno is not set.</td>
</tr>
<tr>
<td>DGX_BADVAL_FAIL</td>
<td>daddr value was not valid. The errno is not set.</td>
</tr>
<tr>
<td>DGX_DCOMPLETE_FAIL</td>
<td>Application received a DMA error detected by the system hardware. The errno is set to the d_complete() return code.</td>
</tr>
<tr>
<td>DGX_UNPINU_FAIL</td>
<td>Application could not unpin the specified user buffer. The errno is set to the unpinu() return code.</td>
</tr>
<tr>
<td>DGX_XMDETACH_FAIL</td>
<td>Application could not detach user space from the physical address. The errno is set to the xmdetach() return code.</td>
</tr>
</tbody>
</table>

Related Information

`pdiag_dd_dma_setup()` and `pdiag_dd_dma_enable()` functions.

pdiag_dd_dma_enable

Purpose

The `pdiag_dd_dma_enable()` function enables and disables a DMA operation. The actual function performed depends on the bus type and operation requested.

Syntax

```c
#include <sys/pdiagex_dds.h>
int32 pdiag_dd_dma_enable( handle, daddr, operation )
pdiag_info_handle_t handle;
pdiag_addr_t daddr;
uint32 operation;
```

Description

Where bus type = BUS_MICRO_CHANNEL and operation is PDIAG_DMA_FLUSH

- The PDIAG_DMA_FLUSH operation uses the specified `daddr` to retrieve the `baddr` and count specified in the corresponding `pdiag_dd_dma_setup()` call. Then the `d_cflush` and `d_bflush` kernel routines are called to do the processor cache and IOCC buffer flushes, respectively.

If users need to change data in the DMA address space, they first change the data in their user space and then call `pdiag_dd_dma_enable()` with a PDIAG_DMA_FLUSH operation. If they need to read data in the DMA address space, they first call `pdiag_dd_dma_enable()` with a PDIAG_DMA_FLUSH operation, and then reads the data in the user space.

- The PDIAG_DMA_FLUSH operation flushes the processor cache and the IOCC buffer. This may be used if a user is required to look at or change the DMA area after a `pdiag_dd_dma_setup()` routine. This routine works only if `pdiag_dd_dma_setup()` is called with `dma_flags = DMA_NOHIDE`. 
This routine is required only if the user wants to read the data before doing \texttt{pdiag_dd_dma_complete}).

Where \(\text{bus type} = \text{BUS\_MICRO\_CHANNEL} \text{ or BUS\_BID} \text{ and operation is PDIAG\_DMA\_DISABLE}\)

\begin{itemize}
  \item The DMA channel for that handle is disabled.
\end{itemize}

Where \(\text{bus type} = \text{BUS\_MICRO\_CHANNEL} \text{ or BUS\_BID} \text{ and operation is PDIAG\_DMA\_ENABLE}\)

\begin{itemize}
  \item The DMA channel for that handle is enabled.
\end{itemize}

**Execution Environment**

The \texttt{pdiag_dd_dma_enable()} function can be called from the process or the interrupt environment on a \texttt{BUS\_MICRO\_CHANNEL} system. The function can only be called from the process environment on a \texttt{BUS\_BID} system.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>Points to \texttt{pdiag_info_handle_t} structure which is returned from \texttt{pdiag_open}().</td>
</tr>
<tr>
<td>daddr</td>
<td>Pointer to the user’s physical DMA address. This is returned by \texttt{pdiag_dd_dma_setup}() routine.</td>
</tr>
<tr>
<td>operation</td>
<td>Type of operation to perform:</td>
</tr>
</tbody>
</table>

- PDIAG\_DMA\_ENABLE
- PDIAG\_DMA\_DISABLE
- PDIAG\_DMA\_FLUSH

**Return Value**

The \texttt{pdiag_dd_dma_enable} function returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DGX_OK</td>
<td>The operation was successful. The \texttt{errno} is not set.</td>
</tr>
<tr>
<td>DGX_INVALID_HANDLE</td>
<td>Specified handle has been closed or was not generated by the \texttt{pdiag_open}() call. The \texttt{errno} is not set.</td>
</tr>
<tr>
<td>DGX_BADVAL_FAIL</td>
<td>Specified \texttt{daddr} is not valid. The \texttt{errno} is not set.</td>
</tr>
<tr>
<td>DGX_FAIL</td>
<td>Application could not transfer data between the processor and the I/O controller (IOCC) data caches. The \texttt{errno} is set to the d_cflush or d_bflush return code.</td>
</tr>
</tbody>
</table>

**Related Information**

The \texttt{pdiag_dd_dma_setup} and \texttt{pdiag_dd_dma_complete} subroutines.

\texttt{pdiag\_shared\_slot}

**Purpose**

Finds all devices that share a slot with the requested device.

**Syntax**

\begin{verbatim}
#include <sys/pdiag\_def.h>
int32 pdiag\_shared\_slot (char *device\_instance)
\end{verbatim}

**Description**

The \texttt{pdiag\_shared\_slot} subroutine finds the siblings of a device and then attempts to determine which siblings are on the same slot. Under some circumstances this function may return more devices sharing a slot than physically exist. This function will always return the device instance at the front of the list, if there are no other devices sharing the slot, the function will return a pointer to the device instance.
Note: This subroutine function will return adapters that are in available and in defined state. It is the responsibility of the calling application to determine if any of the adapters have been removed from the system.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>device_instance</td>
<td>Name of device under test.</td>
</tr>
</tbody>
</table>

Return Value

The `pdiag_shared_slot` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A pointer to the head of a doubly-linked list</td>
<td>Successful return.</td>
</tr>
<tr>
<td>NULL</td>
<td>An error occurred while finding siblings or retrieving data from the ODM.</td>
</tr>
</tbody>
</table>

Related Information

The `pdiag_set_eeh_option` and `pdiag_read_slot_reset` subroutines.

**pdiag_read_slot_reset**

Purpose

Queries the state of the physical reset signal to the I/O Adapter and the Enhanced Error Handling (EEH) slot's capabilities.

Syntax

```c
#include <sys/pdiagex_dds.h>
#include <sys/pdiag_def.h>

int32 pdiag_read_slot_reset( char *device_instance, int32 operation_type )
```

Description

The `pdiag_read_slot_reset` subroutine issues a Run-Time Abstraction service (RTAS) call to query the state of the physical reset signal to the I/O Adapter and the EEH slot's capability.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>device_instance</td>
<td>Name of the device under test.</td>
</tr>
<tr>
<td>operation_type</td>
<td>Integer indicating the function to be performed.</td>
</tr>
</tbody>
</table>

0: Query Reset State

This option returns the slot reset state, indicating if the slot reset is activated or deactivated, and if the I/O adapter is in stopped state or not.

1: Query Slot Capabilities

This option returns the EEH I/O Adapter capabilities, indicating if EEH is supported or not.

Return Value

The `pdiag_read_slot_reset` subroutine returns one of the following values for the Query Reset State operation:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-2</td>
<td>Software error</td>
</tr>
<tr>
<td>-1</td>
<td>Hardware error</td>
</tr>
</tbody>
</table>
Reset deactivated and I/O Adapter is not in the EEH stopped state.

Reset activated and I/O Adapter is not in the EEH stopped state.

I/O Adapter is in the EEH stopped state with the reset signal deactivated and the Load/Store Path is disabled.

I/O Adapter is in the EEH stopped state with the reset signal deactivated and the Load/Store Path is enabled.

I/O Adapter is permanently unavailable.

The `pdiag_read_slot_reset` subroutine returns one of the following values for the Query Slot Capabilities operation:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-2</td>
<td>Software error.</td>
</tr>
<tr>
<td>-1</td>
<td>Hardware error.</td>
</tr>
<tr>
<td>0</td>
<td>EEH not supported.</td>
</tr>
<tr>
<td>1</td>
<td>EEH supported.</td>
</tr>
</tbody>
</table>

**Related Information**

The `pdiag_set_slot_reset` and `pdiag_set_eeh_option` subroutines.

### pdiag_set_eeh_option

**Purpose**

Enables and disables the Enhanced Error Handling (EEH) option for an I/O Adapter, for systems supporting the EEH option.

**Syntax**

```
#include <sys/pdiagex_dds.h>
#include <sys/pdiag_def.h>

int32 pdiag_set_eeh_option( char *device_instance, int32 operation_type )
```

**Description**

The `pdiag_set_eeh_option` subroutine issues Run-Time Abstraction Services (RTAS) calls to enable and disable the EEH option for an I/O Adapter.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>device_instance</td>
<td>Name of the device under test.</td>
</tr>
<tr>
<td>operation_type</td>
<td>Integer indicating the function to be performed.</td>
</tr>
</tbody>
</table>

Supported operations:

- **0**: Disable EEH option:
  - This operation disables the EEH option for the selected I/O Adapter (freeze function is disabled). An error is reported if the EEH function is not supported.

- **1**: Enable EEH option:
  - This operation enables the EEH option for the selected I/O Adapter (freeze function enabled). An error is reported if the EEH function is not supported.

**Return Value**

The `pdiag_set_eeh_option` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-2</td>
<td>A software error occurred.</td>
</tr>
</tbody>
</table>
Return Code | Description
--- | ---
-1 | A hardware error occurred.
0 | The operation was successful.

### Related Information
The `pdiag_set_slot_reset` and `pdiag_read_slot_reset` subroutines.

### pdiag_set_slot_reset

#### Purpose
Activates and deactivates the physical reset signal to the I/O adapter for systems supporting the Enhanced Error Handling (EEH) option.

#### Syntax
```c
#include <sys/pdiagex_dds.h>
#include <sys/pdiag_def.h>

int32 pdiag_set_slot_reset( char *device_instance )
```

#### Description
The `pdiag_set_slot_reset` subroutine resets a single PCI slot by activating and deactivating the slot specific physical reset signal line to the I/O adapter by issuing a Run-Time Abstraction Service (RTAS) call. All required timing parameters will be handled by this subroutine (such as the 100 millisecond minimum reset signal active time for PCI bus).

#### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>device_instance</code></td>
<td>Name of the device under test.</td>
</tr>
</tbody>
</table>

#### Return Value
The `pdiag_set_slot_reset` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-2</td>
<td>A software error occurred.</td>
</tr>
<tr>
<td>-1</td>
<td>A hardware error occurred.</td>
</tr>
<tr>
<td>0</td>
<td>The operation was successful.</td>
</tr>
</tbody>
</table>

- **Kernel Services**
- **Programmed I/O Services**

### PDIAGEX Data Structures
This section describes the data structures used by PDIAGEX.
pdiagex.dds_t

The **pdiagex.dds_t** structure defines the device driver structure (dds) for PDIAGEX. The **pdiagex.dds_t** structure must be initialized with attributes for the resource before calling [pdiag_open](#). The **pdiagex.dds_t** structure is defined in `/usr/include/sys/pdiagex.dds.h` and contains the following fields:

```c
typedef struct {
    uint32 slot_num;       /* slot number of adapter */
    /* BUS DATA */
    uint32 bus_id;         /* Identifies the I/O bus that the DMA */
                          /* channel is to be allocated on. */
    uint32 bus_type;       /* BUS_MICRO_CHANNEL, BUS_60X or BUS_BID */
    uint32 bus_io_addr;    /* Base address of Bus I/O area */
    uint32 bus_io_length;  /* Length (width) of Bus I/O area */
    uint32 bus_mem_addr;   /* Base address of Shared Bus Memory area */
    uint32 bus_mem_length; /* Length (width) of Shared Bus Memory area */
    /* DMA */
    /* Next three are for BUS_MICRO_CHANNEL devices only */
    uint32 dma_bus_mem;    /* Base address of Bus Memory DMA area */
    uint32 dma_bus_length; /* Length (multiple of PAGESIZE) of Bus */
                          /* Memory DMA area in bytes. */
    uint32 dma_lvl;        /* Bus arbitration level */
    uint32 maxmaster;      /* maximum number of concurrent */
                          /* dma_master calls */
    uint32 dma_flags;      /* DMA flags as defined in sys/dma.h. */
                          /* These flags describe what actions to */
                          /* take (master/slave, initialize the */
                          /* channel, etc. Not used by 60X type devices) */
    /* dma_bus_flags is for BUS_BID devices only */
    uint32 dma_bus_flags;  /* Bus flags specific for DMA operation */
    uint32 dma_chan_id;    /* For BUS_MICRO_CHANNEL */
                          /* Dma channel ID is returned as a result */
                          /* of the DMA initialization. */
                          /* For BUS_BID */
                          /* Dma channel ID is the assigned DMA */
                          /* channel for the device. */
                          /* For BUS_60X */
                          /* Dma channel ID is not used */
    /* Interrupt Handler */
    pdiag_addr_t data_ptr; /* Pointer for passing data to interrupt */
    uint32 d_count;        /* Count of bytes of data for interrupt */
    uint32 bus_intr_lvl;   /* Interrupt level */
    uint32 intr_priority;  /* Interrupt priority */
    uint32 intr_flags;     /* Interrupt flags as defined in intr.h */
    /* Attribute Expansion Area */
    pdiag_addr_t attributes; /* Pointer to specific attributes */
}pdiagex.dds_t;
```

pdiagex.opflags_t

The **pdiagex.opflags_t** structure defines the device operations to be used. The **pdiagex.opflags_t** structure is defined in `/usr/include/sys/pdiagex.dds.h` and consists of the following:
typedef struct {
    uint32 memio; /* Type of Memory Operation */
    uint32 count; /* Number of accesses to perform */
    uint32 addr_incr_flag; /* Flag that determines whether the data */
                          /* buffer address and/or the offset */
                          /* address gets incremented on each of */
                          /* count accesses. */
    uint32 intr_level; /* Indicates which environment the */
                      /* calling application is in. */
    struct timestruc_t *times; /* Address of times structure, NULL if */
                      /* not used. */
} pdiagex_opflags_t;

dma_info_t

The `dma_info_t` structure defines the DMA structure used by PDIAGEX. The `dma_info_t` structure is
defined in `/usr/include/sys/pdiagex_sys.h` and contains the following fields:

typedef struct dmast {
    struct dmast *next;
    int firsttcw; /* first TCW used (micro channel only) */
    int last_tcw; /* last TCW used (micro channel only) */
    int dma_flags; /* see /usr/include/sys/dma.h */
    uchar *baddr; /* address of the host buffer to DMA to/from */
    uchar *daddr; /* Phys addr in DMAbus_mem, from */
                  /* diag_dma_master()*/
    uint count; /* size of the DMA data in bytes */
    struct xmem dp; /* Cross Memory descriptor of baddr */
    char pinned; /* NonZero if DMA buffer was pinned */
    char xmattached; /* NonZero if DMA buffer was CrossMemAttached */
    char in_use; /* TRUE if this linked list member is valid */
} dma_info_t;

Parameter   Description

next        Pointer to the next dma_info_t structure in an 'in_use' list.
firsttcw    (Micro Channel devices Only) first page of `pdiagex_ddc_t.dma_bus_mem` used by an active
            DMA master/slave operation.
last_tcw    (Micro Channel devices Only) last page of `pdiagex_ddc_t.dma_bus_mem` used by an active
            DMA master/slave operation.
dma_flags   DMA flags as defined in `<sys/dma.h>`. These flags describe what actions to take (such as,
                        master/slave transfer, initialize the DMA channel, and so on).
*baddr      Address of memory buffer for transfer.
*daddr      Address used to program the DMA master.
count       Size (in bytes) of the DMA transfer.
dp          Address of cross-memory descriptor.
pinned      Nonzero if DMA buffer was pinned.
xmattached  Nonzero if DMA buffer was cross-memory attached.
in_use      Flag for determining if DMA buffer is valid for transfer.
**aioo_struct_t**

The **AIOO_STRUCT_T** structure defines the allocations, initializations, and outstanding operations for each handle. This provides a mechanism for error-recovery cleanup, cleanup of outstanding operations during a close, and general protection from the application. Common code may also be used for cleanup operations.

```c
typedef struct {
    uint AllocIntrptDataMem : 1;
    uint AllocDmaAreaMem : 1;
    uint CopyDDS : 1;
    uint CopyIntrptEnt : 1;
    uint PinIntrptFunct : 1;
    uint PinUIntrptData : 1;
    uint PinDiagExt : 1;
    uint InitIntrptChan : 1;
    uint InitDmaChan : 1;
    uint XmatUIntrptData : 1;
} aioo_struct_t;
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AllocIntrptDataMem</td>
<td>Nonzero if Interrupt data area allocated.</td>
</tr>
<tr>
<td>AllocDmaAreaMem</td>
<td>Nonzero if DMA data area allocated.</td>
</tr>
<tr>
<td>CopyDDS</td>
<td>Nonzero if DDS data was copied to handle.</td>
</tr>
<tr>
<td>CopyIntrptEnt</td>
<td>Nonzero if Intrpt function was in Kernel.</td>
</tr>
<tr>
<td>PinIntrptFunct</td>
<td>Nonzero if Intrpt function was pinned.</td>
</tr>
<tr>
<td>PinUIntrptData</td>
<td>Nonzero if Intrpt data area was pinned.</td>
</tr>
<tr>
<td>PinDiagExt</td>
<td>Nonzero if Pinned PDIAGEX Extension.</td>
</tr>
<tr>
<td>InitIntrptChan</td>
<td>Nonzero if Intrpt channel was initialized.</td>
</tr>
<tr>
<td>InitDmaChan</td>
<td>Nonzero if DMA channel was initialized.</td>
</tr>
<tr>
<td>XmatUIntrptData</td>
<td>Nonzero if Intrpt data area was XMAttached.</td>
</tr>
</tbody>
</table>

**diag_struc_t**

The **diag_struc_t** structure defines the complete data structure returned in the handle for the **pdiag_open**() call. This structure holds all the needed information for all the other **PDIAGEX** function calls.

```c
typedef struct handle {
    struct intr   intr;
    struct        handl *next;
    int           (*intr_func)();
    uchar         *intr_data;>
    struct xmem   udata_dp;
    diagex_dss_t  dds;
    struct timestruc_t itime;
    struct timestruc_t ntime;
    dma_info_t    *dma_info;
    aioo_struct_t aioo;
    char           *scratch_pad;
    uint           sleep_flag;
    uint           sleep_word;
    uint           flag_word;
    struct watchdog wdt;
    struct d_handle *dhandle;
    dma_dio        * dio_st;
    uint           timeout;
} diag_struc_t;
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>intr</td>
<td>Interrupt handler structure as defined in <code>&lt;sys/intr.h&gt;</code>. Needs to be first parameter in <strong>diag_struc_t</strong>.</td>
</tr>
<tr>
<td>(*intr_func)()</td>
<td>Pointer to user's interrupt handler.</td>
</tr>
</tbody>
</table>
Parameter |
--- |
*intr_data* | Pointer to interrupt data. |
udata_dp | Address of cross-memory descriptor for interrupt data. |
dds | Structure that contains the device driver structure (dds) information for PDIAGEX. See the diagex_dds structure defined above. |
itime | Time elapsed for interrupts. Updated at interrupts. |
ntime | Time elapsed for read or write operations. Updated at reads or writes. |
*dma_info* | Pointer to dma_info_t structure which allows multiple DMA operations. See the dma_info_t structure defined above. |
aioo | Set of flags for Allocations, Initializations, and Outstanding Operations. |
scratch_pad | PIO scratch pad for large transfers. |
sleep_flag | *pdiag_dd_watch_for_interrupt*() sets this flag to TRUE if it is sleeping and waiting for the application's interrupt handler to call pdiag_dd_interrupt_notify() This flag is initialized to FALSE and will be set to FALSE after pdiag_dd_watch_for_interrupt() wakes up. |

> The application’s interrupt handler should use this word to determine whether to 'wakeup' pdiag_dd_watch_for_interrupt(). This flag should not be modified by the application’s interrupt handler. |
sleep_word | pdiag_dd_watch_for_interrupt() sleeps on this word until the application’s interrupt handler calls pdiag_dd_interrupt_notify() using this word. |
flag_word | This word should not be modified by the application’s interrupt handler. |
wt | This is the watchdog timer used by the timeout function. |
dhandle | Structure returned by D_MAP_INIT macro which is called in the pdiag_open() function. This handle is used to issue DMA operations to rscp type systems. |
dio_st | Pointer to a DIO structure used in DMA operations. |
timeout | True if watchdog timer expired. |

type kick_io_t

kick_io_t is used to pass kick I/O operation information to the pdiag_dd_kick_hdw_and_watch_for_interrupts_safe_mode() call.

type kick_io_t =
{
  uint32 kick_type; /* Size of the transfer.  * Use IOCHAR8, IOSHORT16, or IOLONG32.  */
  uint32 memio; /* Indicates IO or memory map space. * Must be PDIAG_IO_OP or PDIAG_MEM_OP. */
  uint32 offset; /* Offset in bytes from card base address. */
  uint32 data; /* Right justified data to write. * If IOCHAR8, then use 000000XX, * if IOSHORT16, then use 0000XXXX, * if IOLONG32, then use XXXXXXXX. */
}
### Kernel Services

The following is a list of Kernel Services used by **PDIAGEX**.

<table>
<thead>
<tr>
<th>Kernel Service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>copyin</td>
<td>Copies data between user and kernel memory.</td>
</tr>
<tr>
<td>copyout</td>
<td>Copies data from kernel to user memory.</td>
</tr>
<tr>
<td>curtime</td>
<td>Read the current time into <code>timestruc_t</code> structure.</td>
</tr>
<tr>
<td>d_bflush</td>
<td>Flushes the appropriate I/O controller cache (IOCC), identified by the TCE bus address parameter, on memory-inconsistent platforms.</td>
</tr>
<tr>
<td>d_cflush</td>
<td>Flushes the processor data cache and invalidates any prefetched data that may be in the IOCC buffers on memory-inconsistent platforms.</td>
</tr>
<tr>
<td>e_sleep</td>
<td>Causes process to sleep.</td>
</tr>
<tr>
<td>e_wakeup</td>
<td>Wakes up sleeping process.</td>
</tr>
<tr>
<td>i_clear</td>
<td>Removes an interrupt handler.</td>
</tr>
<tr>
<td>i_disable</td>
<td>Disables interrupt priorities.</td>
</tr>
<tr>
<td>i_enable</td>
<td>Enables interrupt priorities.</td>
</tr>
<tr>
<td>i_init</td>
<td>Defines an interrupt handler.</td>
</tr>
<tr>
<td>io_att</td>
<td>Selects, allocates, and maps a region in the current address space for I/O access.</td>
</tr>
<tr>
<td>io_det</td>
<td>Unmaps and deallocates the region in the current address space at the given address.</td>
</tr>
<tr>
<td>kmod_entrypt</td>
<td>Returns a function pointer to a kernel module’s entry point.</td>
</tr>
<tr>
<td>pincode</td>
<td>Pins the code and data associated with an object file.</td>
</tr>
<tr>
<td>pinu</td>
<td>Pins the specified address range in user or system memory.</td>
</tr>
<tr>
<td>unpincode</td>
<td>Unpins the code and data associated with an object file.</td>
</tr>
<tr>
<td>unpinu</td>
<td>Unpins the specified address range in user or system memory.</td>
</tr>
<tr>
<td>xmalloc</td>
<td>Allocates memory.</td>
</tr>
<tr>
<td>xmattach</td>
<td>Attaches to a user buffer for cross-memory operations.</td>
</tr>
<tr>
<td>xmdetach</td>
<td>Detaches from a user buffer used for cross-memory operations.</td>
</tr>
<tr>
<td>xmemdma</td>
<td>Prepares a page of memory for DMA (used with BUS_60X only).</td>
</tr>
<tr>
<td>xmemin</td>
<td>Copies data to kernel space from a cross-memory attached buffer.</td>
</tr>
<tr>
<td>xmemout</td>
<td>Copies data from kernel space to a cross-memory attached buffer.</td>
</tr>
<tr>
<td>xmfree</td>
<td>Frees allocated memory.</td>
</tr>
</tbody>
</table>

### Programmed I/O Services

The following is a list of Programmed I/O (PIO) macros used by **PDIAGEX**.

<table>
<thead>
<tr>
<th>Macro</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BUS_GETCX</td>
<td>Reads the specified character value from the supplied bus memory, bus I/O, or POS address with built-in exception catching.</td>
</tr>
<tr>
<td>BUS_GETLX</td>
<td>Reads the specified long value from the supplied bus memory, bus I/O, or POS address with built-in exception catching.</td>
</tr>
<tr>
<td>BUS_GETSX</td>
<td>Reads the specified short value from the supplied bus memory, bus I/O, or POS address with built-in exception catching.</td>
</tr>
<tr>
<td>BUS_PUTCX</td>
<td>Writes the specified character value to the supplied bus memory, bus I/O, or POS address with built-in exception catching.</td>
</tr>
<tr>
<td>BUS_PUTLX</td>
<td>Writes the specified long value to the supplied bus memory, bus I/O, or POS address with built-in exception catching.</td>
</tr>
<tr>
<td>BUS_PUTSX</td>
<td>Writes the specified short value to the supplied bus memory, bus I/O, or POS address with built-in exception catching.</td>
</tr>
</tbody>
</table>

The following is a list of Programmed I/O (PIO) macros used by the 64 bit **PDIAGEX**.

<table>
<thead>
<tr>
<th>Macro</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BUS_GETSTR</td>
<td>Reads the specified character value from the supplied bus memory.</td>

## Diagnostic Library

This section provides information on application programming interfaces to administrative and user applications. The calls described are contained in the `/usr/lib/libdiag.a` diagnostic library.

The following is a list of exported programming interfaces available for user applications:

- **Diagnostic Event Log Functions**
  - `dlog_numMatches`
  - `dlog_query`
  - `dlog_query_cleanup`

- **Diagnostic Event Log Data Structures**
  - `dl_fru_src`
  - `dl_partition`
  - `dl_menugoal`
  - `dl_sm`
  - `dl_sm_src`
  - `query_fru`
  - `query_log`
  - `query_output`
  - `query_results`

This section provides information on application programming interfaces to the Diagnostic Applications. The calls described are contained in the `/usr/lib/libdiag.a` diagnostic library.

The following is a list of all the exported programming interfaces available:

- **ODM Object Class Functions**
  - `diag_add_obj`
  - `diag_change_obj`
  - `diag_close_class`
  - `diag_free_list`
  - `diag_get_list`
  - `diag_lock`
  - `diag_open_class`
  - `diag_rm_obj`
  - `diag_unlock`
  - `init_dgodm`
- `term_dgodm`

- **Device Configuration**
  - `configure_device`
  - `diagex_cfg_state`
  - `diagex_initial_state`
  - `get_device_status`
  - `initial_state`

- **FRU Bucket Functions**
  - `addfrub`
  - `addfrub_src`
  - `insert_frub`
  - `add_more_frus`

- **Catalog File Functions**
  - `diag_catopen`
  - `diag_cat_gets`

- **Menu Functions**
  - `diag_popup`
  - `diag_progress`
  - `diag_read`
  - `diag_resource_screen`
  - `diag_task_screen`
  - `diag_asl_clear_screen`
  - `diag_asl_init`
  - `diag_asl_msg`
  - `diag_asl_read`
  - `diag_asl_quit`
  - `diag_display`
  - `diag_display_menu`
  - `diag_emsg`
  - `diag_msg`

- **Device Attributes, Properties**
  - `diag_check_optical_media`
  - `diag_get_device_flag`
  - `diag_get_property`
  - `diag_get_sid_lun`
  - `diag_load_optical_media`
  - `diagUnload_optical_media`
  - `get_cpu_model`
  - `get_dev_desc`
  - `get_diag_att`

- **Diagnostic Event Log Functions**
  - `dlog_getTestMode`
  - `dlog_close`
  - `dlog_find_first`
  - `dlog_find_next`
- dlog_find_sequence
- dlog_formatElogResults
- dlog_freeEntry
- dlog_numMatches
- dlog_open
- dlog_query
- dlog_query_cleanup
- dlog_read
- dlog_same_elogId
- dlog_setEntryType
- dlog_write
- save_davars_ela
- save_davars_mgoal_ela

**dlog_numMatches Subroutine**

**Purpose**
Count the number of diagnostic event log for entries matching an input criteria.
Syntax
#include <diag/diag_log.h>
int dlog_numMatches(query_log *criteria)

Description
The dlog_numMatches subroutine counts the number of diagnostic event log entries matching an input criteria.

Parameters

criteria Criteria used to search the diagnostic event log. Unused fields must be set to 0.
matches Count of the number of entries matching the input criteria.

Return Value
The dlog_numMatches subroutine returns one of the following values:

0 If successful
-1 The diagnostic event log could not be opened
-2 An error occurs reading from the diagnostic event log
-3 The search criteria is invalid
-4 Memory could not be allocated
-5 An error occurred due to too many matches.

dlog_query Subroutine

Purpose
Query the diagnostic event log for entries matching an input criteria.

Syntax
#include <diag/diag_log.h>
int dlog_query(query_log *criteria, query_results *results)

Description
The dlog_query subroutine queries the diagnostic event log for entries matching an input criteria.

Parameters

criteria Criteria used to search the diagnostic event log. Unused fields must be set to 0.
results Structure containing a pointer to a list of entries matching the input criteria. Entries are returned sorted by diagnostic event log sequence number (highest first).

Return Value
The dlog_query subroutine returns one of the following values:

0 If successful
-1 The diagnostic event log could not be opened
-2 An error occurs reading from the diagnostic event log
-3 The search criteria is invalid
-4 Memory could not be allocated
dlog_query_cleanup Subroutine

Purpose
Free memory allocated during a diagnostic event log query.

Syntax
#include <diag/diag_log.h>
int dlog_query_cleanup(query_results *results)

Description
The dlog_query_cleanup subroutine reclaims memory allocated during calls to dlog_query.

Parameters

results Structure containing a pointer to a list of entries matching the input criteria.

Return Value
The dlog_query_cleanup subroutine returns one of the following values:

0 If successful
-1 If unsuccessful

dl_fru_src Structure
The dl_fru_src structure is used with the dl_srn_src. This structure defines a list of FRUs or Procedures needed to resolve the failure.

The dl_fru_src structure is defined in diag_log.h, as:

typedef struct _log_fru_src {
    int type;
    char priority[2];
    char loc[RPA_LOC_SIZE];
    char frupn[RPA_FRU_PN_SIZE];
    char frusn[RPA_FRU_SN_SIZE_NN];
    char ccin[RPA_CCIN_SIZE_NN];
    char proc_id[RPA_PROC_SIZE];
    struct _log_fru_src *nextfru;
} dl_fru_src;

type FRU type, one of the following:
    RPA_FRUTYPE.NORMAL - normal Hardware FRU.
    RPA_FRUTYPE_CODE - code FRU described by procedure id field.
    RPA_FRUTYPE_C_PROC - configuration procedure required.
    RPA_FRUTYPE_M_PROC - maintainence procedure required.
    RPA_FRUTYPE_EXT - external FRU.
    RPA_FRUTYPE_EXT_CODE - external code FRU described by procedure d field
    RPA_FRUTYPE_TOOL - a tool required by another FRU in the list.
    RPA_FRUTYPE_SYMBOL - procedure id for acquiring or working with a FRU.
priority FRU Replacement/Procedure Priority, one of the following:
H High priority and mandatory call-out. Replacing the FRU, or performing the Procedure is mandatory. Multiple call-outs with "H" priority should be acted on as a group.
M Medium priority. Each FRU/Procedure with "M" priority are should be acted on, one at a time, in the order given.
A Medium priority group A. Each FRU/Procedure with "A" priority are should be acted on as a group.
B Medium priority group B. Each FRU/Procedure with "B" priority are should be acted on as a group.
C Medium priority group C. Each FRU/Procedure with "C" priority are should be acted on as a group.
L Low priority. Each FRU/Procedure with "L" priority should be acted on only after all other priority call-outs failed to resolve the problem.

loc Location code of the FRU
frupn FRU Part Number if available
frusn FRU Serial Number if available
ccin CCIN if available
proc_id Procedure Id if available. Mutually exclusive with frupn.
next_fru Pointer to next FRU

dl_partition Structure
The dl_partition structure is contained within the query_output structure. The dl_partition structure is defined in diag_log.h.

The dl_partition structure is defined as:

typedef struct _log_partition {
  int version;
  short callHomeFlg;
  int strSize;
  char *name;
  char *id;
  char *hostname;
  char *typeModel;
  char *sn;
  char *dev_typeModel;
  char *dev_sn;
}dl_partition;

version Reserved for diagnostic use.
callHomeFlg Reserved for diagnostic use.
strSize Combined length of all the following strings.
name Partition name.
id Partition id.
hostname The hostname of the system taken from uname -n.
typeModel Machine type and model.
sn Machine serial number.
dev_typeModel Failing device’s type and model.
dev_sn Failing device’s serial number.
**dl_menugoal Structure**

The `dl_menugoal` structure is contained within the `query_output` structure. The `dl_menugoal` structure is defined in `diag_log.h`.

The `query_fru` structure is defined as:
```c
typedef struct _log_menugoal {
  char *id;
  char *text;
} dl_menugoal;
```

- **id** Six digit menu number.
- **text** Translated menugoal text.

**dl_srn Structure**

The `dl_srn` structure is contained within the `query_output` structure. The `dl_srn` structure is defined in `diag_log.h`.

The `dl_srn` structure is defined as:
```c
typedef struct _log_srn {
  char *name;
  char *srn;
  char *errorText;
  query_fru *frus;
} dl_srn;
```

- **name** SRN's device name.
- **srn** The Service Request Number.
- **errorText** SRN's translated description text.
- **frus** Pointer to the SRN's FRU list.

**dl_srn_src Structure**

The `dl_srn_src` structure is contained within the `query_output` structure, beginning with AIX 5.2.0.30 and later. The `dl_srn_src` structure is defined in the `diag_log.h` header file.

The `dl_srn_src` structure is defined as:
```c
typedef struct _log_srn_src {
  char name[NAME_SIZE];
  char src[MAX_SRC_SIZE];
  char *errorText;
  dl_descText frubDesc;
  dl_fru_src *frus;
  char crid[2];
  unsigned int plid;
  unsigned int action_flags;
  unsigned int subsysid;
  unsigned int event_sev;
  unsigned int refc2;
  unsigned int refc3;
  unsigned int refc4;
  unsigned int refc5;
  unsigned int refc6;
  unsigned int refc7;
  unsigned int refc8;
  unsigned int refc9;
} dl_srn_src;
```
name  Device Name that detected the error.
errorText  Translated description of the failure.
frubDesc  Structure containing the source data for the message pointed to by errorText.

typedef struct _log_descText {
    char   catName[NAME_SIZE];
    short  set;
    short  msg;
} dl_descText;

catName  The message catalog file name.
set  The set id of the message.
msg  The message id of the message.

frus  Pointer to the SRC's FRU list. See the description of dl_fru_src.
crid  Platform error log creator id.
plid  Platform Log Id.

action_flags  Reporting action for this failure. This is stored as a hex value. The following macros are defined in diag_log.h to decode action_flags:

    IS_REPORT_EXTERNALLY(action_flags)
    Returns 1 if the failure should be reported to external programs, like the Service Focal Point.

    IS_CALL_HOME_REQD(action_flags)
    Returns 1 if the failure should be reported automatically to IBM Service.

subsysid  Platform subsystem identifier value. The values are:

    0x10-0x1F Processor subsystem
    0x20-0x2F Memory subsystem
    0x30-0x3F I/O subsystem
    0x40-0x4F I/O adapter, device and peripheral
    0x50-0x5F CEC Hardware
    0x60-0x6F Power/Cooling subsystem
    0x70-0x79 Other subsystem
    0x7A-0x7F Surveillance Error
    0x80-0x8F Platform Error
    0x90-0x9F Software
    0xA0-0xAF External environment
    0xB0-0xFF Reserved

event_sev  Platform event severity value.

    0x10 Recovered error
    0x20 Predictive error, general
    0x21 Predictive error, degraded performance
    0x22 Predictive error, fault may be corrected after platform re-IPL
    0x23 Predictive error, fault may be corrected after IPL, degraded performance
    0x24 Predictive error, loss of redundancy
    0x40 Unrecovered error, general
    0x41 Unrecovered error, bypassed with degraded performance
    0x44 Unrecovered error, bypassed with loss of redundancy
    0x45 Unrecovered error, bypassed with loss of redundancy and performance
    0x48 Unrecovered error, bypassed with loss of function
    0x60 Error on diagnostic test, general
    0x61 Error on diagnostic test, resource may produce incorrect results
query_fru Structure

The query_fru structure is contained within the dl_srn structure. The query_fru structure is defined in diag_log.h.

The query_fru structure is defined as:

typedef struct _log_query_fru {
    char *name;
    int locSize;
    char *locCode;
    char *partNumber;
    char *fruDesc;
    struct _log_query_fru *nextfru;
}query_fru;

name The name of the Field Replacable Unit.
locSize The size of the location code string.
locCode The location code of the FRU (logical or physical).
partNumber The FRU's part number.
fruDesc The FRU's translated description text.
nextfru A pointer to the next FRU in the list. If this is the last FRU, then the pointer is NULL.

query_log Structure

The query_log structure is passed into dlog_query and dlog_numMatches to search the diagnostic event log for entries matching an input criteria. The calling application is responsible for allocating memory for the query_log structure and for inputting valid search criteria into the structure. This structure is defined in diag_log.h.

The query_log structure is defined as:

typedef struct _log_query_crit {
    char *pathname;  /*Path of diagnostic event log file to search*/
    char type;       /*Request entries matching a log template*/
    char identifier[5];  /*Request entries matching identifier*/
    char *name;      /*Request entries matching Resource Name*/
    unsigned int session;  /*Request entries matching Diag Session's PID*/
    char *location;  /*Pointer to logical or physical location code*/
    unsigned int firstSeqNum;  /*Request entries with this sequence number or higher*/
    unsigned int lastSeqNum;  /*Request entries with this sequence number or lower*/
    unsigned int el_identifier;  /*Request entries matching this error log identifier*/
    unsigned int elSeqFirst;  /*Request entries with this error log sequence number or higher*/
    unsigned int elSeqLast;  /*Request entries with this error log sequence number or lower*/
    unsigned int numDays;  /*Request entries x number of days backward or forward*/
    struct tm *startDate;  /*Request entries after this date*/
    struct tm *endDate;  /*Request entries before this date*/
    char *srn;  /*Request entries matching this SRN*/
    char *mgoal;  /*Request entries matching this menugoal*/
    unsigned int maxEntries;  /*Maximum number of entries to return*/
    char *src;  /*Request entries matching this SRC*/
    unsigned int openEvents;  /*Request only entries newer than the last

repair action for a given resource. */
char reserved[100-(sizeof(char*)-(sizeof(unsigned int))];
/*Reserved for future use*/
} query_log;

pathname Path of the diagnostic event log to search. The default path is searched if no path is provided.
type Specifies entries matching a type of log template. I, S, N, E, and X are the valid values for type.
identifier Specifies entries matching a diagnostic event log identifier.
name Specifies entries matching a resource name. This field can be fully or partially qualified. For example, when name is ent*, entries logged against devices beginning with ent will be returned.
session Specifies entries containing a process ID of a diagnostic session.
location Specifies entries containing a location code.
firstSeqNum Specifies entries with this diagnostic event log sequence number or higher.
lastSeqNum Specifies entries with this diagnostic event log sequence number or lower. When searching on a single sequence number use only firstSeqNum.
el_identifier Specifies entries with this AIX error log identifier.
elSeqFirst Specifies entries with this AIX error log sequence number or higher. When searching on a single error log sequence number use elSeqFirst only.
elSeqLast Specifies entries with this AIX error log sequence number or lower. When searching on a single error log sequence number use elSeqLast only.
numDays Searches the diagnostic event log for entries logged this number of days before endDate, or this number of days after startDate, or this number of days before the current date and time. Valid with either startDate or endDate.
startDate Searches the diagnostic event log for entries logged after this date and time. Valid with either numDays or endDate.
srn Searches the diagnostic event log for entries matching this Service Request Number. This field can be fully or partially qualified. For example, when srn is 651*, entries containing Service Request Number starting with 651 will be returned.
mgoal Searches the diagnostic event log for entries matching this menu goal. This field can be fully or partially qualified. For example, when mgoal is 651*, entries containing menu goals with a menu number starting with 651 will be returned.
endDate Searches the diagnostic event log for entries logged before this date and time. Valid with either numDays or startDate.
maxEntries Specifies a maximum number of entries to return. Entries with higher diagnostic event log sequence numbers have a higher priority to be returned. If maxEntries is 0, then all matching entries are returned.
src Beginning with AIX 5.3.0.10 searches the diagnostic event log for entries matching this system reference code (SRC). This field can be fully or partially qualified. For example, when src is BF0*, entries with SRCs beginning with BF0 will be returned.
openEvents Beginning with AIX 5.3.0.10, searches the diagnostic event log for matching entries and that are newer than the last repair action for a given resource. The name field, without wild cards, must also be specified in the query.
reserved Reserved for future use.

query_output Structure
The query_output structure contains information about individual diagnostic event log entries matching the criteria specified by the query_log structure. These structures are contained within the query_results structure returned by dlog_query. Some entries may not contain information for some of the fields within query_output. The query_output structure is defined in diag_log.h.
Beginning with AIX 5.2.0.30 the **query_output** structure is:

```c
typedef struct _log_query_output {
    char type;
    char identifier[5];
    unsigned int el_identifier;
    char *timestamp;
    unsigned int seqNum;
    unsigned int el_seqNum;
    unsigned int session;
    unsigned int testMode;
    char *name;
    char *location;
    dl_srn *srn;
    dl_menugoal *mgoal;
    dl_partition *partition;
    dl_srn_src *srn_src;  /* only in AIX 5.2.0.30 or later */
    char reserved[100-(sizeof (dl_srn_src *))];
} query_output;
```

**type**  
Type of log template used to create the entry. I, S, N, E, and X are the valid values for type.

**identifier**  
Identifier of the diagnostic event log entry.

**timestamp**  
Formatted string of the time at which the diagnostic event log entry was logged.

**seqNum**  
Sequence number for the diagnostic event log entry.

**el_seqNum**  
AIX error log sequence number. The diagnostic event log entry may not be tied to an AIX error log entry.

**session**  
Process id of the diagnostic session that created the entry.
Diagnostics test mode. This is stored as a hex value. The following macros are defined in `diag_log.h` to decode `testMode`:

**IS_CONSOLE_MODE(testMode)**
- Returns 1 when the diagnostic event was in console mode (No-console mode otherwise)

**IS_ADVANCE_MODE(testMode)**
- Returns 1 when the diagnostic event was caused while running advanced diagnostics (Customer diagnostics otherwise)

**IS_NORMAL_BOOT(testMode)**
- Returns 1 when the diagnostics booted normally (Service Boot otherwise)

**IS_NETWORK_BOOT(testMode)**
- Returns 1 when the diagnostics booted from the network

**IS_ELA_MODE(testMode)**
- Returns 1 when the diagnostic event performed error log analysis only

**IS_PD_MODE(testMode)**
- Returns 1 when the diagnostic event performed Problem Determination (System Verification otherwise)

**IS_SYSTEM_CHECK(testMode)**
- Returns 1 when the diagnostic event performed System Checkout (Option Checkout otherwise)

**IS_LOOP_MODE(testMode)**
- Returns 1 when the diagnostic event was in loop mode

**IS_PRETEST_MODE(testMode)**
- Returns 1 when the diagnostic event performed a pretest

**IS_MISSING_MODE(testMode)**
- Returns 1 when the diagnostic event was caused by Missing Options Resolution

**IS_NEW_MODE(testMode)**
- Returns 1 when the diagnostic event was caused while testing new devices

- **name**
  - Name of the resource the entry was logged against.

- **location**
  - Location code for the resource the entry was logged against.

- **srn**
  - Pointer to SRN information. The pointer will be NULL when there is not an SRN.

- **mgoal**
  - Pointer to menugoal information. The pointer will be NULL when there is not a menugoal.

- **partition**
  - Pointer to partition information. The pointer will be NULL when there is no partition information.

- **reserved**
  - Reserved for future use.

---

**query_results Structure**

The `query_results` structure is returned by `dlog_query`. This structure contains the number of entries matching the search criteria and a pointer to the entries matching the search criteria. The calling application is responsible for allocating memory for the `query_results` structure. This structure is defined in `diag_log.h`.

The `query_results` structure is defined as:

```c
typedef struct _log_query_results {
    unsigned int numEntries;
    query_output **entryArray;
}query_results;
```

- **numEntries**
  - Number of entries matching the search criteria.
entryArray Pointer to the entries matching the search criteria.

diag_add_obj

Purpose
Adds a new object into an object class.

Syntax
```c
#include <diag/diagodm.h>
#include <sys/cfgodm.h>
#include <diag/DiagODM.h>

void diag_add_obj (    void *classp,
                        void *p_obj)
```

Description
The `diag_add_obj` subroutine takes as input the class symbol that identifies the object class to change and a pointer to the data structure that contains the object to be added.

Note: `init_dgodm` must be called before starting this subroutine.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>classp</code></td>
<td>A class symbol identifier returned from a <code>diag_open_class</code> subroutine. If the <code>diag_open_class</code> subroutine has not been called, this is the structure name of the class normally defined in either <code>diag/diagodm.h</code>, <code>diag/DiagODM.h</code> file, <code>sys/cfgodm.h</code> file.</td>
</tr>
<tr>
<td><code>p_obj</code></td>
<td>Pointer to an instance of the structure corresponding to the object class referenced by the <code>classp</code> parameter.</td>
</tr>
</tbody>
</table>

Return Value
Upon successful completion, a value of 0 is returned. If the subroutine fails, a -1 is returned.

diag_change_obj

Purpose
Changes an object in the object class.

Syntax
```c
#include <diag/diagodm.h>
#include <sys/cfgodm.h>
#include <diag/DiagODM.h>

void diag_change_obj (    void *classp,
                        void *p_obj)
```

Description
The `diag_change_obj` subroutine takes, as input, the class symbol that identifies the object class to add to and a pointer to the data structure that contains the object to be added. The application must first retrieve the object with a `diag_get_list` subroutine call, change the data values in the returned structure, and then pass that structure to the `diag_change_obj` subroutine.

Note: `init_dgodm` must be called before starting this subroutine.
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classp</td>
<td>A class symbol identifier returned from a diag_open_class subroutine. If the diag_open_class subroutine has not been called, then this is the structure name of the class normally defined in either the diag/diagodm.h file, diag/DiagODM.h file, or sys/cfgodm.h file.</td>
</tr>
<tr>
<td>p_obj</td>
<td>Pointer to an instance of the structure corresponding to the object class referenced by the classp parameter.</td>
</tr>
</tbody>
</table>

Return Value

Upon successful completion, a value of 0 is returned. If the subroutine fails, a -1 is returned.

diag_close_class

Purpose

Closes an object class.

Syntax

```c
#include <diag/diagodm.h>
#include <sys/cfgodm.h>
#include <diag/DiagODM.h>

int diag_close_class ( void *classp )
```

Description

The diag_close_class subroutine can be called to close an object class.

Note: init_dgodm must be called before starting this subroutine.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classp</td>
<td>A class symbol identifier returned from a diag_open_class subroutine. If the diag_open_class subroutine has not been called, then this is the structure name of the class normally defined in either the diag/diagodm.h file, diag/DiagODM.h file, or sys/cfgodm.h file.</td>
</tr>
</tbody>
</table>

Return Value

Upon successful completion, a value of 0 is returned. If the subroutine fails, a -1 is returned.

diag_free_list

Purpose

Frees memory previously allocated for a diag_get_list subroutine.

Syntax

```c
#include <diag/diagodm.h>
#include <sys/cfgodm.h>
#include <diag/DiagODM.h>

int diag_free_list ( void *p_obj,
                     struct listinfo *info )
```
Description
The `diag_free_list` subroutine recursively frees up a tree of memory object lists that were allocated for a `diag_get_list` subroutine.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_obj</td>
<td>Points to the array of structures returned from the <code>diag_get_list</code> subroutine.</td>
</tr>
<tr>
<td>info</td>
<td>Points to the <code>listinfo</code> structure returned from the <code>diag_get_list</code> subroutine.</td>
</tr>
</tbody>
</table>

Return Value
Upon successful completion, a value of 0 is returned. If the subroutine fails, a -1 is returned.

diag_get_list

Purpose
Retrieves all objects in an object class that match the specified criteria.

Syntax

```c
#include <diag/diagodm.h>
#include <sys/cfgodm.h>
#include <diag/DiagODM.h>

void * diag_get_list (void *classp, char *criteria, struct listinfo *info, int max_expect, int depth)
```

Description
The `diag_get_list` subroutine takes an object class and criteria as input, and returns a list of objects that satisfy the input criteria. The subroutine opens and closes the object class around the get if the object class was not previously opened. If the object class was previously opened, the subroutine leaves the object class open when it returns.

Note: `init_dgodm` must be called before starting this subroutine.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classp</td>
<td>Class symbol identifier returned from a <code>diag_open_class</code> subroutine. If the <code>diag_open_class</code> subroutine has not been called, then this is the structure name of the class normally defined in either the <code>diag/diagodm.h</code> file, <code>diag/DiagODM.h</code> file, or <code>sys/cfgodm.h</code> file.</td>
</tr>
<tr>
<td>criteria</td>
<td>String that contains the qualifying criteria for selecting objects.</td>
</tr>
<tr>
<td>info</td>
<td>Structure containing information about the retrieval of the objects.</td>
</tr>
<tr>
<td>max_expect</td>
<td>Expected number of objects to be returned. This is used to control the increments in which storage for structures is allocated, to reduce the <code>realloc</code> subroutine copy overhead.</td>
</tr>
<tr>
<td>depth</td>
<td>Number of levels to recurse for objects with linking descriptors.</td>
</tr>
</tbody>
</table>

Return Value
Upon successful completion, a pointer to an array of C language structures containing the objects is returned. If no match is found, NULL is returned. If the `diag_get_list` fails, a value of -1 is returned.
**diag_lock**

**Purpose**
Obtain an ODM lock for the specified file

**Syntax**
```
#include <diag/odmi.h>
int diag_lock(char *file)
```

**Description**
The `diag_lock` subroutine calls `odm_lock()` for a specified file. It waits 5 seconds if a lock cannot be immediately granted.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file</td>
<td>Name of the file to lock</td>
</tr>
</tbody>
</table>

**Return Value**
The `diag_lock` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;0</td>
<td>If successful</td>
</tr>
<tr>
<td>0</td>
<td>File is already locked</td>
</tr>
<tr>
<td>-1</td>
<td>Error</td>
</tr>
</tbody>
</table>

**diag_open_class**

**Purpose**
Opens an object class.

**Syntax**
```
#include <diag/diagodm.h>
#include <sys/cfgodm.h>
#include <diag/DiagODM.h>

void *diag_open_class ( void *classp)
```

**Description**
The `diag_open_class` subroutine can be called to open an object class.

**Note:** `init_dgodm` must be called before starting this subroutine.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classp</td>
<td>The structure name of the class normally defined in either the <code>diag/diagodm.h</code> file, <code>diag/DiagODM.h</code> file, or <code>sys/cfgodm.h</code> file.</td>
</tr>
</tbody>
</table>

**Return Value**
Upon successful completion, a class symbol identifier for the object class is returned. If the subroutine fails, a -1 is returned.
diag_rm_obj

Purpose
Deletes objects from an object class.

Syntax
#include <diag/diagodm.h>
#include <sys/cfgodm.h>
#include <diag/DiagODM.h>

void diag_rm_obj ( void *classp, char *criteria )

Description
The diag_rm_obj subroutine deletes objects from an object class.

Note: init_dgodm must be called before starting this subroutine.

Parameters
Parameter       Description
classp          Class symbol identifier returned from a diag_open_class subroutine. If the
diag_open_class subroutine has not been called, then this is the structure name of the
class normally defined in either diag/diagodm.h, diag/DiagODM.h file or sys/cfgodm.h
file.

criteria        String containing the qualifying criteria for selecting objects to delete.

Return Value
Upon successful completion, the number of objects deleted is returned. If the subroutine fails, a -1 is
returned.

diag_unlock

Purpose
Release an ODM lock

Syntax
#include <odmi.h>
int diag_unlock(int *id)

Description
The diag_unlock subroutine releases an odm lock.

Parameters
Parameter       Description
id              Lock id to release

Return Value
The diag_unlock subroutine returns one of the following values:

Parameter       Description
0               If successful
-1              Error occurred while trying to unlock a lock
init_dgodm, term_dgodm

Purpose
Initializes or stops the Object Data Manager.

Syntax
int init_dgodm ( )

int term_dgodm ( )

Description
The init_dgodm subroutine issues an odm_initialize call to the Object Data Manager. This should be done at the beginning of the Diagnostic Application (DA).

The term_dgodm subroutine issues an odm_terminate call to the Object Data Manager. This should be done at the end of the DA.

Parameters
Takes no parameters.

Return Value
A value of 0 is always returned.

configure_device, initial_state

Purpose
Puts a device and parentage into the available state.

Restores a device and parentage to their initial state before configuration.

Syntax
#include <diag/diagodm.h>
#include <sys/cfgodm.h>
#include <sys/cfgdb.h>

int configure_device ( name )
char *name;

int initial_state ( state, name )
int state;
char *name;

Description
The configure_device subroutine is used to put a device into the AVAILABLE state (for testing) if the device is presently DEFINED or STOPPED. Also the parentage of the device is checked, and their states also put into AVAILABLE state if necessary.

The initial_state subroutine is used to restore the device and parentage back to their initial state (after testing).

Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Identifies the device.</td>
</tr>
<tr>
<td>state</td>
<td>Indicates the previous state of the device.</td>
</tr>
</tbody>
</table>
Return Value
The following values are returned:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFINED</td>
<td>Device was previously in the DEFINED state.</td>
</tr>
<tr>
<td>AVAILABLE</td>
<td>Device is already in the AVAILABLE state.</td>
</tr>
<tr>
<td>STOPPED</td>
<td>Device was previously in the STOPPED state.</td>
</tr>
<tr>
<td>-1</td>
<td>Error configuring the device.</td>
</tr>
</tbody>
</table>

**diagex_cfg_state**

**Purpose**
Puts the device under test in the DIAGNOSE state.

**Syntax**
```
#include <diag/diag.h>

int diagex_cfg_state ( device_name )
char *device_name;
```

**Description**
The `diagex_cfg_state` subroutine unconfigures the device, and its children if necessary, to set the device into the DIAGNOSE state. Original states of all devices changed will be saved. Use [diagex_initial_state](#) to put the changed devices back to their original states.

The global variable `diag_cfg_errno` will be set to the return value of the method invoked for the device.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>device_name</td>
<td>Name of the device under test.</td>
</tr>
</tbody>
</table>

**Return Value**
The `diagex_cfg_state` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful return.</td>
</tr>
<tr>
<td>-1</td>
<td>Software error.</td>
</tr>
<tr>
<td>1</td>
<td>Child device cannot be unconfigured.</td>
</tr>
<tr>
<td>2</td>
<td>Device cannot be unconfigured.</td>
</tr>
<tr>
<td>3</td>
<td>Device cannot be put into DIAGNOSE state.</td>
</tr>
</tbody>
</table>

**diagex_initial_state**

**Purpose**
Puts the device under test back to its original state.

**Syntax**
```
#include <diag/diag.h>

int diagex_initial_state ( device_name )
char *device_name;
```
Description
The `diagex_initial_state` subroutine puts the device, and its children if necessary, back to the original state before the `diagex_cfg_state` routine was called.

Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>device_name</code></td>
<td>Name of the device under test.</td>
</tr>
</tbody>
</table>

Return Value
The `diagex_initial_state` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful return.</td>
</tr>
<tr>
<td>-1</td>
<td>Software error.</td>
</tr>
<tr>
<td>4</td>
<td>Device cannot be restored to DEFINE state.</td>
</tr>
<tr>
<td>5</td>
<td>Device cannot be restored to AVAILABLE state.</td>
</tr>
<tr>
<td>6</td>
<td>Child device cannot be restored to original state.</td>
</tr>
</tbody>
</table>

`get_device_status`

Purpose
Returns the device’s current configuration status.

Syntax
```
#include <sys/cfgdb.h>

int get_device_status ( device_name )
char * device_name;
```

Description
The `get_device_status` subroutine returns the current device configuration status. The status is obtained by returning the value of the CuDv status field of the device.

Note: `[init_dgodm]` must be called before starting this subroutine.

Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>device_name</code></td>
<td>Character pointer to the name of the device.</td>
</tr>
</tbody>
</table>

Return Value
The `get_device_status` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFINED</td>
<td>Device is in the DEFINED state.</td>
</tr>
<tr>
<td>AVAILABLE</td>
<td>Device is in the AVAILABLE state.</td>
</tr>
<tr>
<td>STOPPED</td>
<td>Device is in the STOPPED state.</td>
</tr>
<tr>
<td>DIAGNOSE</td>
<td>Device is in the DIAGNOSE state.</td>
</tr>
<tr>
<td>-1</td>
<td>System error obtaining device status.</td>
</tr>
</tbody>
</table>
addfrub

Purpose
Concludes a field replaceable unit (FRU) goal.

Syntax
```c
#include <diag/da.h>
int addfrub (fptr)
struct fru_bucket *fptr;
```

Description
The `addfrub` subroutine associates a FRU with the device currently being tested. The `TMIpPut` object class identifies the device currently being tested.

Parameters
```
Parameter | Description
--- | ---
fptr | Pointer to a structure of type fru_bucket, which is defined as follows:
```
```c
struct fru_bucket {
    char dname[NAMESIZE];
    short ftype;
    short sn;
    short rcode;
    short rmsg;
    struct {
        int conf;
        char fname[NAMESIZE];
        char floc[LOCSIZE];
        short fmsg;
        char fru_flag;
        char fru_exempt;
    } frus[MAXFRUS];
};
```
```
dname | Names the device under test.
ftype | Indicates the type of FRU Bucket being added to the system. The following values are defined:
```
FRUB1 | The FRUs include the resource that failed, its parent, and any cables needed to attach the resource to its parent.
FRUB2 | This FRU Bucket is similar to FRU Bucket FRUB1, but does not include the parent resource.
```
```
| Parameter | Description
--- | ---
| sn | Source number of the failure. The source number is usually set to the led field of the PdDV object class by the `insert_frub` subroutine. If the sn set by the `insert_frub` subroutine is not the desired value, the calling subroutine should set sn to the desired value after the `insert_frub` subroutine and before the `addfrub` subroutine. |
**Parameter**

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>rcode</strong></td>
</tr>
<tr>
<td>Reason code associated with the failure.</td>
</tr>
</tbody>
</table>

**Note:** A Service Request Number is formatted as follows:

\[
\text{SSS} - \text{RRR}
\]

where SSS is the *sn* and RRR is the *rcode*.

Some devices may use a different nomenclature for their service request numbers. For this special case, the *sn* parameter indicates how the *rcode* value should be formatted. If *sn* = 0, then *rcode* is interpreted as decimal. If *sn* = -1, then *rcode* is interpreted as a 4-digit hexadecimal number.

If *sn* = -2, then the object class **DAVars** is searched for an attribute of Errorcode. This allows the displaying of 8 digit hex Error Codes. The diagnostic application is responsible for setting up a **DAVars** object similar to the following:

**DAVars:**

- **dbname:** <device name under test>
- **vname:** Error_code   "Error_code is an ascii string"
- **vtype:** DIAG_STRING   "Literal value"
- **val:** <8 digit hex character string>

See the [getdavar/putdavar] subroutine for more information.

**rmsg**  
Message number of the text describing the reason code. The set number of the text is predefined by the *PSet* field in the **Predefined Diagnostic Resources** object class.

**conf**  
Indicates whether an FRU is valid. A value of 0 indicates an invalid FRU. No other FRUs are displayed once an invalid FRU is found in the FRU bucket.

However, if *fname* contains the string **REF-CODE**, then the *fmsg* and *conf* values are used to make the 8-digit ref code.

For AIX 4.3.2 and earlier versions, this field indicates the probability of failure associated with the named FRU.

**fname**  
Names the FRU.

The parameters *floc* and *fmsg* must be specified, if *fname* is not represented in the **Customized Devices** object class. Otherwise, they should be set to 0.

**floc**  
Location of *fname*.

**fmsg**  
Message number of the text describing *fname*. The set number is predefined by the *PSet* descriptor in the **Predefined Diagnostic Resources** object class.

**fru_flag**  
Flag used by the Diagnostic Applications (DA) in determining which FRU to use in the **frus[]** structure. The following values are defined:

- **NOT_IN_DB**  
The FRU is not represented in the config database.

- **DA_NAME**  
  *frus[]*.fname should be the name of the device being tested.

- **PARENT_NAME**  
  *frus[]*.fname should be the name of the parent of the device being tested.

- **CHILD_NAME**  
  *frus[]*.fname should be the name of the child of the device being tested.

- **NO_FRU_LOCATION**  
The FRU name will be left blank, and the FRU location code will be set to the location of the device under test (*dbname*).
Parameter | Description
--- | ---
fru_exempt | Indicates that the designated FRU will not be absorbed as a result of chip/FRU integration. The following values are defined:

**EXEMPT**
FRU cannot be integrated (For example, fuse, cable, displays, etc.) This value should be the most-used value, and should be used in conjunction with the fru_flag field. Examples are:

<table>
<thead>
<tr>
<th>FRU</th>
<th>fru_flag</th>
<th>fru_exempt</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device being tested</td>
<td>DA_NAME</td>
<td>EXEMPT</td>
</tr>
<tr>
<td>Parent of device</td>
<td>PARENT_NAME</td>
<td>EXEMPT</td>
</tr>
<tr>
<td>CABLE</td>
<td>NOT_IN_DB</td>
<td>EXEMPT</td>
</tr>
</tbody>
</table>

**NONEXEMPT**
FRU can be integrated (generally, any specific chip set).

**Note**: DAs do not have to return **MAXFRU frus**. The Diagnostic Controller processes frus[ ] from 0..MAXFRU-1, while conf>0.

**Return Value**
Upon successful completion, a value of 0 is returned. If the addfrub subroutine is unsuccessful, then a value of -1 is returned.

**addfrub_src**

**Purpose**
Concludes a collection of field replacement units (FRUs) with a platform specific System Reference Code (SRC).

**Syntax**
```
#include <diag/da.h>

int addfrub_src (fptr)
struct fru_bucket_src *fptr;
```

**Description**
The addfrub_src subroutine associates a collection of FRUs with a failure detected by the device currently being tested. The TMInput object class identifies the device currently being tested.

**Note**: addfrub() should be used when reporting a Service Request Number (SRN). insert_frub() should be called before addfrub() to fill in some of the fru_bucket data. addfrub_src() should be used when reporting an System Reference Code (SRC). Then, entire contents of the fru_bucket should be filled in by the caller before calling addfrub_src(), thus there is no corresponding call to insert_frub for fru_bucket_src.
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>fptr</em></td>
<td>Pointer to a structure of type <em>fru_bucket_src</em>, which is defined below. The entire structure must be filled out before calling <code>addfrub_src</code>. Any optional or unknown values should be set to NULL (0).</td>
</tr>
</tbody>
</table>

```c
struct fru_bucket_src {
    char dname[NAMESIZE]; /* Resource Name */
    char src[RPA_SRC_SIZE_NN]; /* Primary reference code */
    unsigned int refc2; /* Extended reference code - word 2 */
    unsigned int refc3; /* Extended reference code - word 3 */
    unsigned int refc4; /* Extended reference code - word 4 */
    unsigned int refc5; /* Extended reference code - word 5 */
    unsigned int refc6; /* Extended reference code - word 6 */
    unsigned int refc7; /* Extended reference code - word 7 */
    unsigned int refc8; /* Extended reference code - word 8 */
    unsigned int refc9; /* Extended reference code - word 9 */
    int rmsg; /* Failure description */
    char crid[2]; /* Platform error creator id */
    unsigned int plid; /* Platform Log Id */
    unsigned int subsysid; /* Subsystem Id */
    unsigned int event_sev; /* Event Severity */
    int action_flags; /* Error Action Flags */
    int errlg_seq; /* Error Log Sequence Number */
    frus_src_t *frus; /* Linked list of FRUs for SRC */
};
```

- **dname** Names the device under test.
- **src** System Reference Code. The Primary Reference Code is the 1st 8 characters of this 32 character string. The Primary Reference Code is required, the remainder of the string is optional.
- **refc2** Extended reference code word 2 (required).
- **refc3 - refc9** Optional additional extended reference code words 3 - 9. Should be 0 if not present.
- **rmsg** Message number of the text describing the failure. The set number of the text is predefined by the PSet field in the predefined Diagnostic Resources object class.
- **crid** ASCII character representing the subsystem creating the error log reporting the failure. Use NULL (0) if this failure is not from platform error log analysis.
- **plid** Unique identifier for this failure.
- **subsysid** Platform Error Log Subsystem ID, otherwise 0.
- **event_sev** Platform Error Log Severity, otherwise 0.
- **action_flags** Flags defining reporting action for this failure. The values can be or’ed together.

#### Bit Action

- **RPA_REPORT_EXTERNALLY**
  Report this failure to external programs like the Service Focal Point.

- **RPA_CALL_HOME_REQD**
  Only valid with **RPA_REPORT_EXTERNALLY**, this failure should be reported automatically to IBM Service.

- **NO_FAULT_INDICATOR**
  If the plid is zero and this bit is set, the system’s fault indicator will not be turned on for this failure.

- **errlg_seq** Error log sequence number of originating error.

Chapter 3. Diagnostic Components 127
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>frus</strong></td>
<td>Optional linked list of FRUs as described in the following structure. This list is not necessary if the SRC completely describes the failure and resolution actions.</td>
</tr>
<tr>
<td><strong>type</strong></td>
<td>FRU type. One of the following:</td>
</tr>
</tbody>
</table>
|          | **RPA_FRUTYPE_NORMAL**  
|          | Normal Hardware FRU. |
|          | **RPA_FRUTYPE_CODE**  
|          | Code FRU described by procedure id field. |
|          | **RPA_FRUTYPE_C_PROC**  
|          | Configuration procedure required. |
|          | **RPA_FRUTYPE_M_PROC**  
|          | Maintenance procedure required. |
|          | **RPA_FRUTYPE_EXT**  
|          | External FRU. |
|          | **RPA_FRUTYPE_EXT_CODE**  
|          | External code FRU described by procedure field. |
|          | **RPA_FRUTYPE_TOOL**  
|          | A tool required by another FRU in the list. |
|          | **RPA_FRUTYPE_SYMBOL**  
|          | Procedure id for acquiring or working with a FRU. |
| **priority** | FRU Replacement/Procedure Priority. One of the following: |
|          | **H**  
|          | High priority and mandatory call-out. Replacing the FRU, or performing the Procedure is mandatory. Multiple call-outs with H priority should be acted on as a group. |
|          | **M**  
|          | Medium priority. Each FRU/Procedure with M priority should be acted on, one at a time, in the order given. |
|          | **A**  
|          | Medium priority group A. Each FRU/Procedure with A priority should be acted on as a group. |
|          | **B**  
|          | Medium priority group B. Each FRU/Procedure with B priority should be acted on as a group. |
|          | **C**  
|          | Medium priority group C. Each FRU/Procedure with C priority should be acted on as a group. |
|          | **L**  
|          | Low priority. Each FRU/Procedure with L priority should be acted on only after all other priority call-outs have failed to resolve the problem. |
| **loc** | Location code |
| **pn** | FRU Stocking Part Number if available, mutually exclusive with proc_id. |
| **proc_id** | Procedure Id if available, mutually exclusive with pn. |
| **ccin** | CCIN, if available and only if pn is available. |
| **sn** | FRU Serial Number, if available, and only if pn is available. |
| **next_fru** | Pointer to the next frus_src structure. |
Return Value

0 Upon successful completion.
-1 If the `addfrub` subroutine is unsuccessful.

**insert_frub**

**Purpose**
Updates FRU Bucket.

**Syntax**

```c
#include <diag/tm_input.h>
#include <diag/da.h>

long insert_frub ( tminput, frub )
struct tm_input *tminput;
struct fru_bucket *frub;
```

**Description**

The `insert_frub` subroutine gets a device’s FRU name and source number from the **Customized Device** object class and places them into a structure of type `fru_bucket`. The calling routine specifies through the `fru_flag` member of the `FRU Bucket` structure whether the FRU name is for device `x` or the FRU parent of `x`.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>tminput</code></td>
<td>Identifies the device <code>x</code> (specifically, <code>tminput.dname</code>).</td>
</tr>
<tr>
<td><code>frub</code></td>
<td>Pointer to the FRU Bucket structure to be updated.</td>
</tr>
</tbody>
</table>

This function should be called before `addfrub`.

**Return Value**

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned.

**add_more_frus**

**Purpose**
Adds additional FRUs to an FRU bucket previously added by the `addfrub()` subroutine.

**Syntax**

```c
#include <diag/da.h>

int add_more_frus(fptr)
struct fru_bucket *fptr;
```

**Description**

The `add_more_frus` subroutine takes an additional set of FRUs and adds them to an existing FRU bucket that was previously added via the `addfrub()` subroutine.

This subroutine can add up to `MAXFRUS` number of FRUs per invocation, but can be called multiple times. This subroutine is called only after calling `addfrub()`. The input `fru_bucket` should have the same data as sent to `addfrub()`, except for the FRUs array.

**Note:** `init_dgodm` must be called before starting this subroutine.
Parameters

Parameter | Description
--- | ---
fptr | Pointer to a structure of type `fru_bucket`, that is almost identical to the structure used in the call to `addfrub()`. The only difference should be the array of FRUs structure that contains the additional FRUs that should be added to the existing FRU bucket. For more information, refer to the `fru_bucket` definition in the `addfrub()` subroutine.

Return Value

The `add_more_frus` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>On successful completion</td>
</tr>
<tr>
<td>-1</td>
<td>If ODM error</td>
</tr>
<tr>
<td>-2</td>
<td>If <code>addfrub()</code> did not add <code>MAXFRUS</code> number of FRUs (i.e. this function should not have been called)</td>
</tr>
</tbody>
</table>

**diag_catopen**

**Purpose**

Opens a diagnostic catalog message file.

**Syntax**

```c
#include <diag/diago.h>

nl_catd diag_catopen (filename, reserved)
char* filename;
int reserved;
```

**Description**

The `diag_catopen` subroutine is used to open a catalog message file. It first searches the normal catalog directory as specified by the `$LANG` and `$NLSPATH` environment variables. If the catalog file is not found, the function searches the default catalog directory.

**Parameters**

Parameter | Description
--- | ---
filename | Catalog file name to be opened.

**Return Value**

The `diag_catopen` subroutine returns a `nl_catd` catalog descriptor.

**diag_cat_gets**

**Purpose**

Obtains catalog messages from `NLSPATH` or default diagnostic catalog directory.

**Syntax**

```c
#include <diag/diago.h>

char *diag_cat_gets (fdes, setid, msgid)
nl_catd fdes;
unsigned short setid;
unsigned short msgid;
```
Description
The **diag_cat_gets** subroutine is used to get messages from a catalog file. It first searches the normal catalog directory as specified by the `SLANG` and `NLSPATH` environment variables. If the set and message is not found, the function searches the default catalog directory.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\textit{fdes}</td>
<td>Open catalog file descriptor returned from the \texttt{diag_catopen} system call.</td>
</tr>
<tr>
<td>\textit{setid}</td>
<td>Set ID of the message in the catalog.</td>
</tr>
<tr>
<td>\textit{msgid}</td>
<td>Message ID of the message in the catalog that serves as the format string.</td>
</tr>
</tbody>
</table>

Return Value
The **diag_cat_gets** subroutine returns a character pointer to the message string.

\textbf{diag_popup}

Purpose
Creates a popup window with message text.

Syntax
```c
#include <diag/diag_screen.h>

long diag_popup ( char * fmt, [, name, ...] )

char * fmt;
```

Description
The **diag_popup** subroutine displays a popup window.

Parameters
The parameters are similar to those of the standard I/O library subroutine \texttt{printf()}. There is a 2000 character limit on the length of the message.

Return Value
The **diag_popup** subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIAG_CANCEL</td>
<td>Cancel key was entered.</td>
</tr>
<tr>
<td>DIAG_ENTER</td>
<td>Enter Function key was entered.</td>
</tr>
<tr>
<td>DIAG_EXIT</td>
<td>Exit Function key was entered.</td>
</tr>
</tbody>
</table>

\textbf{diag_progress}

Purpose
Displays progress messages by the Diagnostic Applications and Diagnostic Tasks.

Syntax
```c
#include <diag/diag_screen.h>

#include <diag/diag.h>

void diag_progress ( screen_progress )

screen_prog_t *screen_progress;
```
Description
The diag_progress subroutine displays the progress indicators used by Diagnostic Applications and other Diagnostic Tasks.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>screen_prog</td>
<td>Screen Progress Information. This structure defines the progress message to be displayed and the percentage complete.</td>
</tr>
<tr>
<td></td>
<td>int max_value (Used for Web-based System Manager progress bars) Maximum value.</td>
</tr>
<tr>
<td></td>
<td>int current_value (Used for Web-based System Manager progress bars) Current value.</td>
</tr>
<tr>
<td></td>
<td>char * progress_msg</td>
</tr>
<tr>
<td></td>
<td>Progress message to be displayed.</td>
</tr>
</tbody>
</table>

diag_read

Purpose
Reads user input.

Syntax
#include <diag/diag_screen.h>
#include <diag/diag.h>
long diag_read ( screen_info, wait, buffer )

screen_info_t *screen_info;
int wait;
char * buffer;

Description
The diag_read subroutine reads the keyboard buffer.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>screen_info</td>
<td>Screen Information. This structure defines the screen type and screen ID. Only the screen_type is used.</td>
</tr>
<tr>
<td></td>
<td>short screen_type</td>
</tr>
<tr>
<td></td>
<td>Screen Type.</td>
</tr>
<tr>
<td></td>
<td>• INFORMATIVE</td>
</tr>
<tr>
<td></td>
<td>• TRANSITIONAL</td>
</tr>
<tr>
<td></td>
<td>• DIALOG</td>
</tr>
<tr>
<td></td>
<td>• SINGLE_SELECTION</td>
</tr>
<tr>
<td></td>
<td>• MULTIPLE_SELECTION</td>
</tr>
<tr>
<td>wait</td>
<td>If TRUE, causes this subroutine to wait until the user presses one of the keys allowed by the screen_type. If this parameter is FALSE, then this subroutine does not wait for the user input but processes anything typed ahead just as it would if the parameter were TRUE.</td>
</tr>
<tr>
<td>buffer</td>
<td>Allocated by the application. It is used to return the values entered by the user. The buffer size must not be greater than 100 bytes. (Currently not implemented).</td>
</tr>
</tbody>
</table>
**diag_resource_screen**

**Purpose**
Displays menus commonly used by Diagnostic Applications (DA).

**Syntax**
```c
#include <diag/diag_screen.h>
#include <diag/diag.h>

long diag_resource_screen ( screen_info, screen_data, screen_msg )

screen_info_t *screen_info;
screen_data_t *screen_data;
screen_msg_t screen_msg[];
```

**Description**
The `diag_resource_screen` subroutine displays menus commonly used by Diagnostic Applications.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>screen_info</td>
<td>Screen Information. This structure defines the screen type and screen ID.</td>
</tr>
</tbody>
</table>
| short screen_type | Screen Type.  
|                 | • INFORMATIVE  
|                 | • TRANSITIONAL  
|                 | • SINGLE_SELECTION |
| short screen_id | Screen Identifier.  
|                 | • TESTING_MENU  
|                 | • ANALYZE_ERROR_LOG  
|                 | • ANALYZE_POST  
|                 | • ANALYZE_FIRMWARE  
|                 | • ANALYZE_CHECKSTOP  
|                 | • ANALYZE_SUBSYS |
| short screen_key | Identifies extra function keys for screen.  
<p>|                 | • DIAG_HELP_KEY |
| long item_selected | Indicates the selected item in the list, if <code>screen_type</code> is SINGLE_SELECTION. First selectable item in <code>screen_msg</code> would have a 1 returned, second selectable item would have a 2 returned, and so on. |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>screen_data</strong></td>
<td>Screen Data. This structure contains all data needed to construct the screen.</td>
</tr>
<tr>
<td>nl_catd</td>
<td>fdes</td>
</tr>
<tr>
<td>long menu_number</td>
<td>Menu number that is displayed, right-justified, as a hex number at the top-right corner of the screen.</td>
</tr>
<tr>
<td>char * resource_name</td>
<td>The name of the resource being tested. <em>(tminput→dname)</em></td>
</tr>
<tr>
<td>char * location_code</td>
<td>The logical location code of the resource being tested. <em>(tminput→dnameloc)</em></td>
</tr>
<tr>
<td>short test_mode</td>
<td>The test mode (ADVANCED, NON_ADVANCED) this session is running in. <em>(tminput→advanced)</em></td>
</tr>
<tr>
<td>short loop_mode</td>
<td>Indicates whether Loop Mode has been selected. <em>(tminput→loopmode)</em></td>
</tr>
<tr>
<td>short lcount</td>
<td>Total number of passes made. This value is used only when <strong>loop_mode</strong> is not set to <strong>LOOPMODE_NOTLM</strong>.</td>
</tr>
<tr>
<td>short lerrors</td>
<td>Total number of errors encountered. This value is used only when <strong>loop_mode</strong> is not set to <strong>LOOPMODE_NOTLM</strong>.</td>
</tr>
<tr>
<td>short msg_count</td>
<td>Total number of messages in the <strong>screen_msg</strong> structure.</td>
</tr>
</tbody>
</table>

| **screen_msg** | The **screen_msg** structure contains an array of setid's and msgid's used to construct the text (or body) of the screen. This includes all messages except the last line, or INSTRUCTION line. This structure is not required for a TRANSITIONAL screen type, use NULL for the **screen_msg** argument. |
| short set_num | The set number containing the message text. |
| short msg_num | The message number containing the message text. |
| char * message | Text message to use in place of `<set_num, msg_num>`. This is useful if string substitution was required in order to build the message text. This text will take precedence over the `<set_num, msg_num>` if not NULL. |
| short msg_type | Flag indicating the type of message to be displayed. |
|                | • HELP_MSG Only one message of this type allowed. This help message will always be associated with the screen, and not any particular line. |
|                | • SELECTABLE_MSG |
|                | • INFO_MSG |

**NOTES:**
• This structure must be built exactly for a **SINGLE_SELECTION** screen type. `screen_msg[0..n]` MUST have the `msg_type` set to **SELECTABLE_MSG** for all selectable messages.

• `screen_msg[n+1]` MUST have the `msg_type` set to **INFO_MSG** if you want some kind of information displayed to the user before the **INSTRUCTION** line.

• The help message, if any, should be last.

**Return Value**
The **diag_resource_screen** subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIAG_OK</td>
<td>Successful return.</td>
</tr>
<tr>
<td>DIAG_MALLOCFAILED</td>
<td>Memory allocation was unsuccessful.</td>
</tr>
<tr>
<td>DIAG_ENTER</td>
<td>Enter Function key was entered.</td>
</tr>
<tr>
<td>DIAG_EXIT</td>
<td>Exit Function key was entered.</td>
</tr>
<tr>
<td>DIAG_CANCEL</td>
<td>Cancel Function key was entered.</td>
</tr>
<tr>
<td>DIAG_HELP</td>
<td>Help Function key was entered.</td>
</tr>
<tr>
<td>DIAG_FAIL</td>
<td>Invalid data structure, software error</td>
</tr>
</tbody>
</table>

**diag_task_screen**

**Purpose**
Displays menus commonly used by Diagnostic Tasks.

**Syntax**
```
#include <diag/diag_screen.h>
#include <diag/diag.h>

long diag_task_screen ( screen_info, screen_task_data, screen_task_msg )

screen_info_t *screen_info;
screen_task_t *screen_task_data;
screen_task_msg_t screen_task_msg[];
```

**Description**
The **diag_task_screen** subroutine displays menus commonly used by Diagnostic Tasks.
## Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>screen_info</td>
<td>Screen Information. This structure defines the screen type.</td>
</tr>
</tbody>
</table>
| **short** screen_type | Screen Type.  
  - INFORMATIVE  
  - TRANSITIONAL  
  - DIALOG  
  - SINGLE_SELECTION  
  - MULTIPLE_SELECTION |
| short screen_id | Screen Identifier - Not Used.                                               |
| short screen_key | Identifies extra function keys for screen.  
  - DIAG_LIST_KEY  
  - DIAG_HELP_KEY if screen_type is INFORMATIVE |
| long item_selected | Indicates the selected item in the list, if screen_type is SINGLE_SELECTION. First selectable item in screen_msg would have a 1 returned, second selectable item would have a 2 returned, and so on.  
  For a MULTIPLE_SELECTION screen_type, this field is used to keep track of the current selection for subsequent calls until the COMMIT function key is used. |
<p>| screen_task_data | Screen Data. This structure contains all data needed to construct the screen. |
| <strong>nl_catd</strong> fdes | Catalog file descriptor.                                                     |
| long menu_number | Menu number that is displayed, right-justified, as a hex number at the top-right corner of the screen. |
| short msg_count | Total number of messages in the screen_task_msg structure.                  |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>screen_task_msg</td>
<td>The <code>screen_task_msg</code> structure contains an array of setid’s and msgid’s used to construct the text (or body) of the screen. This includes all except the last line, or Instruction line.</td>
</tr>
<tr>
<td>short set_num</td>
<td>The set number containing the message text.</td>
</tr>
<tr>
<td>short msg_num</td>
<td>The message number containing the message text.</td>
</tr>
<tr>
<td>char * message</td>
<td>Text message to use in place of <code>&lt; set_num, msg_num &gt;</code>. This is useful if string substitution was required in order to build the message text. This text will take precedence over the <code>&lt; set_num, msg_num &gt;</code> if not NULL.</td>
</tr>
<tr>
<td>short help_set_num</td>
<td>The set number containing the message text when the HELP key is pressed. Help message text is line sensitive, and is normally used when the <code>msg_type</code> is set to <code>SELECTABLE_MSG</code> or <code>DIALOG_MSG</code>.</td>
</tr>
<tr>
<td>short help_msg_num</td>
<td>The message number containing the message text when the HELP key is pressed. Help message text is line sensitive, and is normally used when the <code>msg_type</code> is set to <code>SELECTABLE_MSG</code> or <code>DIALOG_MSG</code>.</td>
</tr>
</tbody>
</table>
| short msg_type      | Flag indicating if text is help, selectable, dialog, or information.  
|                     | - TITLE_MSG  
|                     | - SELECTABLE_MSG  
|                     | - DIALOG_MSG  
|                     | - INFO_MSG     |
| char leading_char   | A specific character to be displayed before the message text. Note that this is also used as the mechanism to determine which selectable items had been selected on a MULTIPLE_SELECTION screen. |
| long line_num       | Internal screen line number.                                                                                                                                                                                |
| char op_type        | Type of operation allowed on this field                                                                                                                                                                    |
| char entry_type     | Type of (user) entry allowed in the field                                                                                                                                                                   |
| char required       |  
|                     | - DIAG_YES  
|                     | - DIAG_YES_NON_EMPTY  
|                     | - DIAG_EXCEPT_WHEN_EMPTY  
|                     | - DIAG_NO = default  
|                     | - DIAG_YES or DIAG_YES_NON_EMPTY means display required flag                                                                                     |
| char changed        | DIAG_YES, DIAG_NO = default; field changed from default value                                                                                                                                              |
| char * disp_values  | disp. text of allowed/default choice(s, separated by ",")                                                                                                                                                 |
| char * data_value   | MUST point to string (buffer) of size (entry_size + 1) if there is ANY way values may be changed (typein/list/ring)                                                                                         |
| long entry_size     | maximum size of (data_)value that can be entered OR returned (include a “return” of anything from disp_values)                                                                                           |
| long cur_value_index| 0 origin index of default value                                                                                                                                                                            |
| long default_value_index |                                                                                                                                                    |

**NOTES:**

Chapter 3. Diagnostic Components 137
• The `screen_task_msg` structure must be built exactly for **SINGLE_SELECTION**, **MULTIPLE_SELECTION**, and **DIALOG** screen types. `screen_msg[0]` MUST have the `msg_type` set to **TITLE_MSG** for the TITLE line.
• `screen_msg[1..n]` MUST have the `msg_type` set to **SELECTABLE_MSG** or **DIALOG_MSG** for all selectable/dialog messages.
• `screen_msg[n+1]` MUST have the `msg_type` set to **INFO_MSG** if you want some kind of information displayed to the user before the INSTRUCTION line.

**Return Value**
The `diag_task_screen` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIAG_OK</td>
<td>Successful return.</td>
</tr>
<tr>
<td>DIAG_MALLOCFAILED</td>
<td>Memory allocation was unsuccessful.</td>
</tr>
<tr>
<td>DIAG_ENTER</td>
<td>Enter Function key was entered.</td>
</tr>
<tr>
<td>DIAG_EXIT</td>
<td>Exit Function key was entered.</td>
</tr>
<tr>
<td>DIAGANCEL</td>
<td>Cancel Function key was entered.</td>
</tr>
<tr>
<td>DIAG_HELP</td>
<td>Help Function key was entered.</td>
</tr>
<tr>
<td>DIAG_LIST</td>
<td>List Function key was entered.</td>
</tr>
<tr>
<td>DIAG_FAIL</td>
<td>Invalid data structure, software error</td>
</tr>
<tr>
<td>DIAG_COMMIT</td>
<td>Commit function key was entered.</td>
</tr>
</tbody>
</table>

**diag_asl_clear_screen**

**Purpose**
Clears the screen.

**Syntax**
```
#include <diag/diago.h>

long diag_asl_clear_screen ( )
```

**Description**
The `diag_asl_clear_screen` subroutine is used to clear the screen.

**Parameters**
Takes no parameters.

**Return Value**
The following values are returned:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIAG_ASL_OK</td>
<td>Successful return.</td>
</tr>
<tr>
<td>DIAG_ASL_FAIL</td>
<td>Not called following <code>diag_asl_init</code> and before <code>diag_asl_quit</code>.</td>
</tr>
</tbody>
</table>

**diag_asl_init**

**Purpose**
Initializes the user interface.

**Syntax**
```
#include <diag/diago.h>

long diag_asl_init ( name )
char *name;
```
Description
The `diag_asl_init` subroutine is used to initialize the user interface and should be the first call made to the user interface.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Identifies any options. This field has the following values:</td>
</tr>
<tr>
<td></td>
<td><strong>DEFAULT</strong> Type ahead allowed.</td>
</tr>
<tr>
<td></td>
<td><strong>NO_TYPE_AHEAD</strong> Type ahead not allowed.</td>
</tr>
</tbody>
</table>

Return Value

The following values are returned:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIAG_ASL_OK</td>
<td>Successful return.</td>
</tr>
<tr>
<td>DIAG_ASL_ERR_NO_SUCH_TERM</td>
<td>Specified TERM entry does not exist.</td>
</tr>
<tr>
<td>DIAG_ASL_ERR_TERMINFO_GET</td>
<td>TERMINFO get failed.</td>
</tr>
<tr>
<td>DIAG_ASL_ERR_NO_TERM</td>
<td>TERM entry missing.</td>
</tr>
<tr>
<td>DIAG_ASL_ERR_INITSCR</td>
<td>nitscr() failed.</td>
</tr>
<tr>
<td>DIAG_ASL_ERR_SCREEN_SIZE</td>
<td>Screen/window size less than minimum.</td>
</tr>
</tbody>
</table>

**diag_asl_msg**

Purpose

Creates a pop-up window with message text.

Syntax

```c
#include <diag/diago.h>

long diag_asl_msg ( fmt, [ , name, ... ] )
char *fmt;
```

Description

The `diag_asl_msg` subroutine should only be used by service aids to display a pop-up window with informational text.

Parameters

The parameters are similar to those of the standard I/O library subroutine `printf`.

Return Value

The following values are returned:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIAG_ASL_CANCEL</td>
<td>Cancel key was pressed.</td>
</tr>
<tr>
<td>DIAG_ASL_ENTER</td>
<td>Enter key was pressed.</td>
</tr>
<tr>
<td>DIAG_ASL_HELP</td>
<td>Help key was pressed.</td>
</tr>
<tr>
<td>DIAG_ASL_LIST</td>
<td>List key was pressed.</td>
</tr>
<tr>
<td>DIAG_ASL_COMMAND</td>
<td>Command key was pressed.</td>
</tr>
<tr>
<td>DIAG_ASL_COMMIT</td>
<td>Commit key was pressed.</td>
</tr>
</tbody>
</table>
diag_asl_read

Purpose
Reads user input.

Syntax
#include <diag/diago.h>

long diag_asl_read ( screen_code, wait, buf )
ASL_SCREEN_CODE screen_code;
int wait;
char *buf;

Description
The diag_asl_read subroutine reads the keyboard buffer.

Parameters

Parameter | Description
--- | ---
screen_code | Identifies the set of function keys that should be active.
wait | If True, causes this subroutine to wait until the user presses one of the keys allowed by the screen_type. If this parameter is False, then this subroutine does not wait for the user input but processes anything typed ahead just as it would if the parameter were True.
buf | Allocated by the application. It is used to return the values entered by the user. If used, this buffer MUST be at least ASL_READ_BUF_SIZE. Normally this value should be set to NULL. When NULL, only the function key pressed is returned.

Return Value
The diag_asl_read subroutine returns one of the following values:

Return Value | Description
--- | ---
DIAG_ASL_OK | Successful return.
DIAG_ASL_FAIL | Failure reading data.
DIAG_ASL_CANCEL | Cancel key was entered.
DIAG_ASL_ENTER | Enter key was entered.
DIAG_ASL_EXIT | Exit key was entered.

diag_asl_quit

Purpose
Terminates the user interface.

Syntax
#include <diag/diago.h>

long diag_asl_quit ( name )
char *name;

Description
The diag_asl_quit subroutine is used to end the user interface and should be the last call made to the user interface.
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Identifies any options. This field has the following values:</td>
</tr>
<tr>
<td></td>
<td>DCTRL Used by Diagnostic Controller only.</td>
</tr>
<tr>
<td></td>
<td>DEFAULT Used by all other applications.</td>
</tr>
</tbody>
</table>

Return Value

The following value is always returned:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful return.</td>
</tr>
</tbody>
</table>

`diag_display`

Purpose

Displays a menu and reads the user's response.

Syntax

```c
#include <diag/diago.h>

long diag_display ( mnum, fdes, msglist, proctype,
                    scrtype, menutype, menuinfo )
```

Description

The `diag_display` subroutine displays a menu that has multiple user selections and reads the user's response.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mnum</td>
<td>Menu number that is displayed, right-justified, as a hex number at the top-right corner of the screen.</td>
</tr>
<tr>
<td>fdes</td>
<td>Open catalog file descriptor returned from the <code>diag_catopen</code> system call.</td>
</tr>
<tr>
<td>msglist</td>
<td>Array of set numbers and message IDs. The <code>msglist</code> parameter must be ended by a Null element.</td>
</tr>
<tr>
<td>proctype</td>
<td>Specifies the type of operation to be performed. This parameter has the following values:</td>
</tr>
<tr>
<td></td>
<td>DIAG_MSGONLY The specified messages are retrieved from the catalog, but not displayed. The application writer should update the <code>menuinfo</code> parameter and restart the <code>diag_display</code> subroutine with the <code>msglist</code> parameter equal to Null.</td>
</tr>
<tr>
<td></td>
<td>DIAG_IO The list of messages specified by <code>msglist</code> or, if that is Null, those in the array <code>menuinfo</code>, are displayed in the format specified by the <code>menutype</code> parameter.</td>
</tr>
<tr>
<td>scrtype</td>
<td>Specifies the type of screen to be displayed, where each type determines the format of the output and the active function keys for the user.</td>
</tr>
<tr>
<td>menutype</td>
<td>Defined in the file <code>/usr/include/asl.h</code>. If this parameter is equal to Null, the default version is used. Otherwise, the application's version is used.</td>
</tr>
</tbody>
</table>
Parameter | Description
--- | ---
menuinfo | Defined in the file `/usr/include/asl.h`. If this field is *not* equal to Null, it is initialized with the retrieved messages.

**Return Value**
The `diag_display` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIAG_ASL_OK</td>
<td>Successful return.</td>

</tbody>
</table>

**diag_display_menu**

**Purpose**
Displays menus commonly used by Diagnostic Applications (DA).

**Syntax**
```
#include <diag/diago.h>

#include <diag/diag.h>

long diag_display_menu ( msgid, mnum, substitution, lcount, lerrors )
long msgid;
long mnum;
char *substitution[];
int lcount;
int lerrors;
```

**Description**
The `diag_display_menu` subroutine displays commonly used menus.
Parameters

Parameter | Description
--- | ---
msgid | Message ID number defined in dcda.msg. Currently, the following message IDs are defined:

CUSTOMER_TESTING_MENU
ADVANCED_TESTING_MENU
LOOPMODE_TESTING_MENU
NO_MICROCODE_MENU
NO_DIAGMICROCODE_MENU
NO_DDFILE_MENU

NO_HOT_KEY

DEVICE_INITIAL_STATE_FAILURE

mnum | Menu number that is displayed, right-justified, as a hex number at the top-right corner of the screen.

substitution | Used to pass in strings to be substituted in the menu. This must be an array of three (3) character pointers. The device descriptive text is the first element. The device name as it comes from TMInput->dname is the second, and the location code is the third.

lcount | Used to allow the loop-count value to be displayed. This value is used only when mnum is set to LOOPMODE_TESTING_MENU.

lerrors | Used to allow the number of errors value to be displayed. This value is used only when mnum is set to LOOPMODE_TESTING_MENU.

Return Value

The diag_display_menu subroutine returns one of the following values:

Return Value | Description
--- | ---
DIAG_ASL_OK | Successful return.
DIAG_ASL_ARGS1 | Both the msglist and menuinfo parameters were Null.
DIAG_ASL_ARGS2 | DIAG_MSGONLY option was specified, but no messages were named.
DIAG_MALLOCFAILED | Memory allocation was unsuccessful.
DIAG_ASL_ENTER | Enter Function key was entered.
DIAG_ASL_EXIT | Exit Function key was entered.
DIAG_ASL_CANCEL | Cancel Function key was entered.
DIAG_ASL_HELP | Help Function key was entered.
DIAG_ASL_LIST | List Function key was entered.
DIAG_ASL_COMMIT | Commit Function key was entered.
DIAG_ASL_PRINT | Print Function key was entered.

diag_emsg

Purpose
Displays error messages.

Note: Diagnostic Applications (DAs) should not use this subroutine.
Syntax

```c
#include <diag/diago.h>

long diag_emsg ( fdes, setid, msgid [,val,... ] )
nl_catd fdes;
unsigned short setid;
unsigned short msgid;
```

Description

The `diag_emsg` subroutine displays an error message. Normally used with service aids.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fdes</code></td>
<td>Open catalog file descriptor returned from the <a href="#">diag_catopen</a> system call.</td>
</tr>
<tr>
<td><code>setid</code></td>
<td>Set ID of the message in the catalog.</td>
</tr>
<tr>
<td><code>msgid</code></td>
<td>Message ID of the message in the catalog that serves as the format string.</td>
</tr>
<tr>
<td><code>val</code></td>
<td>Values that are optional and variable in number are inserted in the specified message according to the conventions assumed by the printf() subroutine in the standard I/O library. The format is specified by the message referenced by the catalog set and message ID.</td>
</tr>
</tbody>
</table>

Return Value

The `diag_emsg` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIAG_ASL_OK</td>
<td>Successful return.</td>
</tr>
<tr>
<td>DIAG_ASL_CANCEL</td>
<td>Cancel key was entered.</td>
</tr>
<tr>
<td>DIAG_ASL_EXIT</td>
<td>Exit key was entered.</td>
</tr>
</tbody>
</table>

`diag_msg`, `diag_msg_nw`

Purpose

Displays simple menus.

Syntax

```c
#include <diag/diago.h>

long diag_msg ( mnum, fdes, setid, msgid [,val, ... ] )
long mnum;
nl_catd fdes;
unsigned short setid;
unsigned short msgid;

long diag_msg_nw ( mnum, fdes, setid, msgid [,val, ... ] )
long mnum;
nl_catd fdes;
unsigned short setid;
unsigned short msgid;
```

Description

The `diag_msg` subroutine displays the specified text and obtains the user’s response. The screen is automatically cleared upon completion.

The `diag_msg_nw` subroutine displays the specified text but does not wait for the user to respond. The screen is not automatically cleared.
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mnum</td>
<td>Menu number that is displayed, right-justified, as a hex number at the top-right corner of the screen.</td>
</tr>
<tr>
<td>fdes</td>
<td>Open catalog file descriptor returned from the <code>diag_catopen</code> system call.</td>
</tr>
<tr>
<td>setid</td>
<td>Set ID of the message in the catalog.</td>
</tr>
<tr>
<td>msgid</td>
<td>Message ID of the message in the catalog that serves as the format string.</td>
</tr>
<tr>
<td>val</td>
<td>Values that are optional and variable in number are inserted in the specified message according to the conventions assumed by the <code>printf()</code> subroutine in the standard I/O library. The format is specified by the message referenced by the catalog set and message ID.</td>
</tr>
</tbody>
</table>

Return Value

The `diag_msg` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIAG_ASL_OK</td>
<td>Successful return.</td>
</tr>
<tr>
<td>DIAG_ASL_CANCEL</td>
<td>Cancel key was entered.</td>
</tr>
<tr>
<td>DIAG_ASL_EXIT</td>
<td>Exit key was entered.</td>
</tr>
</tbody>
</table>

`diag_check_optical_media`

Purpose

Checks the status of the optical drive.

Syntax

```
#include <diag.h>

int diag_check_optical_media(device_name)
char * device_name
```

Description

The `diag_check_optical_media` function will take an optical media device name passed by the caller and check the status of the drive and unmount it if possible.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>device_name</td>
<td>This is the name of the optical media drive requested by the caller to be accessed. <code>/dev/cdXX</code> where XX is the number of the optical drive as listed by the ODM.</td>
</tr>
</tbody>
</table>

Return Value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-2</td>
<td>Fail due to software error.</td>
</tr>
<tr>
<td>-1</td>
<td>Fail. Optical device is in use.</td>
</tr>
<tr>
<td>0</td>
<td>Success. The optical device chosen is ready for use.</td>
</tr>
</tbody>
</table>

`diag_get_device_flag`

Purpose

Obtain device flag from residual data information.

Attention: This diagnostic library function has been removed in AIX 5.2 but the information has been left in for reference.
Syntax
#include <diag/diag.h>
#include <sys/residual.h>

int diag_get_device_flag (char *device_name, long *Flag)

Description
The `diag_get_device_flag` subroutine searches residual data for an object matching the device specified by `device_name`. The value of the `Flags` field as defined in the `DEVICE_ID` structure for the device is returned in the `Flag` argument.

Implementation Specifics
POWER-based

Parameters

Parameter | Description
--- | ---
`device_name` | Pointer to a character string containing the logical name of the device.
`Flag` | Pointer to a long integer where the value of the `Flag` field in the `DEVICE_ID` structure as defined by `sys/residual.h` header file will be written.

Return Value
Upon successful completion, a 0 is returned if the device flag information was retrieved successfully. If the `diag_get_device_flag` fails, a value of -1 is returned.

diag_get_property

Purpose
Obtain property value from Common Hardware Reference Platform (CHRP) firmware for a resource.

Syntax
#include <diag/diag.h>

char *diag_get_property (char *device_name, char *property_name, int *property_length)

Description
The `diag_get_property` subroutine searches the Open Firmware device tree to obtain the value of a property associated with the specified resource. The resource must be a valid ODM resource name with a corresponding Open Firmware device tree node. If the resource’s corresponding node is not found in the Open Firmware device tree, or if the property value is not found, then a char *NULL is returned.

Implementation Specifics
POWER-based

Parameters

Parameter | Description
--- | ---
`device_name` | Pointer to a character string containing the logical name of the device.
`property_name` | Pointer to a character string containing the property to find.
`property_length` | Contains total number of characters pointed to by the return character value.
Return Value
Upon successful completion, a character string is returned containing the value (or values) of the property requested. Multiple values may be separated by a NULL value. If the resource is not valid, or the property value is not found, then a char *NULL is returned.

diag_get_sid_lun

Purpose
Returns the SCSI ID and Logical Unit Number (LUN) from a SCSI address.

Syntax
#include <diag/diag.h>

int diag_get_sid_lun ( scsiaddr, sid_addr, lun_addr )
char *scsiaddr;
uchar *sid_addr;
uchar *lun_addr;

Description
The diag_get_sid_lun subroutine returns the SCSI ID and logical unit number associated with a SCSI address for a device. The SCSI address must be in the format used by the connwhere field in CuDv object class.

Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scsiaddr</td>
<td>Pointer to the address of the SCSI device. This is the connwhere field of the device. Format is &quot;x,y&quot; where x is the SCSI ID, and y is the logical unit number.</td>
</tr>
<tr>
<td>sid_addr</td>
<td>Pointer to the SCSI ID of the device.</td>
</tr>
<tr>
<td>lun_addr</td>
<td>Pointer to the logical unit number of the device.</td>
</tr>
</tbody>
</table>

Return Value
The diag_get_sid_lun subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful return.</td>
</tr>
<tr>
<td>-1</td>
<td>Error. Incorrect format for SCSI address.</td>
</tr>
</tbody>
</table>

diag_load_optical_media

Purpose
Loads optical media data and makes it available to the caller.

Syntax
#include <diag.h>

int diag_load_optical_media(device_name, mnt_path)
char*  device_name
char*  mnt_path

Description
The diag_load_optical_media function will take an optical media device name passed by the caller and mount its data over a returned mounted path for the caller to access the data.
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>device_name</td>
<td>This is the name of the optical media drive requested by the caller to be accessed. /dev/cdXX where XX is the number of the optical drive as listed by the ODM.</td>
</tr>
<tr>
<td>mnt_path</td>
<td>This is the mounted path returned to the caller to access the optical media data (for example, /usr/lpp/diagnostics/mnt/cdXX) where XX is the drive number given to the optical drive by the ODM.</td>
</tr>
</tbody>
</table>

Return Value

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIAG_NO_MEDIA</td>
<td>Fail. No Media found in the drive.</td>
</tr>
<tr>
<td>-2</td>
<td>Fail. Software error.</td>
</tr>
<tr>
<td>-1</td>
<td>Fail. Device is in use.</td>
</tr>
<tr>
<td>0</td>
<td>The mount was successful.</td>
</tr>
</tbody>
</table>

diag_unload_optical_media

Purpose

Unmounts the optical media drive and makes it available to the caller.

Syntax

```c
#include <diag.h>

int diag_unload_optical_media(device_name)
char * device_name
```

Description

The `diag_unload_optical_media` function takes an optical media device name passed by the caller and unmounts the drive, if and only if, the drive is not already mounted or in use by another application.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>device_name</td>
<td>This is the name of the optical media drive requested by the caller to be accessed. /dev/cdXX where XX is the number of the optical drive as listed by the ODM.</td>
</tr>
</tbody>
</table>

Return Value

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-2</td>
<td>Fail. Software error.</td>
</tr>
<tr>
<td>-1</td>
<td>Fail. Device is in use.</td>
</tr>
<tr>
<td>0</td>
<td>The mount was successful.</td>
</tr>
</tbody>
</table>

get_cpu_model

Purpose

Returns the CPU model number.

Syntax

```c
#include <diag/modid.h>

unsigned int get_cpu_model ( model_code )
int model_code;
```
Description
The get_cpu_model subroutine gets the CPU model number.

-init_dgodm must be called before starting this subroutine.

Implementation Specifics
POWER-based

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>model_code</td>
<td>Attribute stored in the CuAt database for the sys0 model code. The unsigned integer returned by the function is the raw model code obtained from the IPL control block. Macros are defined in modid.h. These macros can be used to determine the following information:</td>
</tr>
<tr>
<td>Package Type</td>
<td>Tower, Rack, or Desktop.</td>
</tr>
<tr>
<td>Speed</td>
<td>Low, Medium, High, or Turbo Charged.</td>
</tr>
<tr>
<td>Machine Type</td>
<td>Release 1, RSC, Release 2, or PowerPC®.</td>
</tr>
</tbody>
</table>

Return Value
Upon successful completion, the model code as stored in the iplcb structure is returned. Otherwise, a value of -1 is returned.

get_dev_desc

Purpose
Returns the device’s descriptive text.

Syntax
char * get_dev_desc ( device_name )
char * device_name;

Description
The get_dev_desc subroutine gets the descriptive text associated with the device. This text is stored in the catalog field of the PdDv entry for the device. This is usually found in the /usr/lib/methods/devices.cat file for most devices. Other devices may use different catalogs.

Note: -init_dgodm must be called before starting this subroutine.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>device_name</td>
<td>Character pointer to the name of the device.</td>
</tr>
</tbody>
</table>

Return Value
Upon successful completion, a char pointer to a text string in memory is returned. Otherwise, a value of -1 is returned.

get_diag_att

Purpose
Reads an attribute from the predefined database PDiagAtt.
Syntax
#include <diag/modid.h>

int get_diag_att ( type, attribute, conversion, byte_count, value )

char *type;
char *attribute;
char conversion;
int *byte_count;
void *value;

Description
The get_diag_att subroutine gets attributes from the predefined diagnostic database PDiagAtt.

Parameters
The arguments are defined as follows:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>Device type, which should be Class/SubClass/Type string. This fully qualified string reduces the chance of finding two objects having the same Type value in the PdDv object class.</td>
</tr>
<tr>
<td>attribute</td>
<td>Attribute name to get from the Predefined Attribute Object Class.</td>
</tr>
<tr>
<td>conversion</td>
<td>The data type to which the attribute is to be converted, including the following:</td>
</tr>
<tr>
<td></td>
<td>'s' = string</td>
</tr>
<tr>
<td></td>
<td>rep = s</td>
</tr>
<tr>
<td></td>
<td>'b' = byte sequence</td>
</tr>
<tr>
<td></td>
<td>rep = s (for example &quot;0x56FFE67&quot;)</td>
</tr>
<tr>
<td></td>
<td>'l' = long</td>
</tr>
<tr>
<td></td>
<td>rep = n</td>
</tr>
<tr>
<td></td>
<td>'i' = int</td>
</tr>
<tr>
<td></td>
<td>rep = n</td>
</tr>
<tr>
<td></td>
<td>'h' = short (half)</td>
</tr>
<tr>
<td></td>
<td>rep = n</td>
</tr>
<tr>
<td></td>
<td>'f' = float</td>
</tr>
<tr>
<td></td>
<td>rep = n</td>
</tr>
<tr>
<td></td>
<td>'c' = char</td>
</tr>
<tr>
<td></td>
<td>rep = n, or s</td>
</tr>
<tr>
<td>byte_count</td>
<td>Number of bytes (for byte sequence only).</td>
</tr>
<tr>
<td>value</td>
<td>Pointer to where the converted attribute value is returned.</td>
</tr>
</tbody>
</table>

Return Value
Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned.

dlog_getTestMode

Purpose
Return the value of the dlog_testmode attribute in CDiagAtt for the specified device.

Syntax
#include <diag/diag_log.h>

int dlog_getTestMode(char *name)
Description
The dlog_getTestMode subroutine gets a CDiagAtt object for the specified device with an attribute of dlog_testmode. The value of the dlog_testmode is returned.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Character pointer to the name of the device</td>
</tr>
</tbody>
</table>

Return Value
Upon successful completion, the test mode is returned. Otherwise, -1 is returned if the object does not exist.

dlog_close

Purpose
Closes the Diagnostic Event Log opened by dlog_open.

Syntax
```
#include <diag/diag_log.h>

int dlog_close(dl_info *info)
```

Description
The dlog_close subroutine closes the log file opened with dlog_open. It will also free the memory allocated with dlog_open.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>info</td>
<td>Pointer to structure of format:</td>
</tr>
<tr>
<td>typedef struct _log_info {</td>
<td></td>
</tr>
<tr>
<td>int fd; /* File descriptor */</td>
<td></td>
</tr>
<tr>
<td>int lockId; /* ODM Lock id */</td>
<td></td>
</tr>
<tr>
<td>dl_att <em>dlAtt; /</em> Pointer to log attributes */</td>
<td></td>
</tr>
<tr>
<td>dl_einfo <em>dlArray; /</em> Pointer to log array */</td>
<td></td>
</tr>
</tbody>
</table>
  | } dl_info;
  |
  | typedef struct _log_einfo { |
  | int version; /* Entry Version */ |
  | char logType; /* Log Type - I,S,N,E,X */ |
  | unsigned int size; /* Entry Size */ |
  | unsigned int offset; /* Offset from the file's beginning */ |
  | } dl_einfo;
  |
  | typedef struct _log_att { |
  | int version; /* Version */ |
  | unsigned int numEntries; /* number of log entries */ |
  | unsigned int lastIndex; /* index of latest entry */ |
  | unsigned int nextSeqNum; /* sequence number of next log entry */ |
  | unsigned int maxLogSize; /* maximum size of log */ |
  | unsigned int arrayOffset; /* array offset */ |
  | unsigned int wrapCount; /* number of times file has wrapped */ |
  | } dl_att;
  |

Return Value
Upon successful completion, 0 is returned. Otherwise, a value of -1 is returned.
**dlog_find_first**

**Purpose**
Finds the first diagnostic log entry that matches the specified criteria.

**Syntax**
```
#include <diag/diag_log.h>

int dlog_find_first(dl_info *dlogInfo, char *criteria, dlSearch *filter, dlEntry **results)
```

**Description**
The `dlog_find_first` subroutine finds the first diagnostic log entry that matches the specified criteria. It also parses the search criteria and uses this to initialize the dlSearch structure for subsequent searches. It allocates memory for the matching entry, and returns the array index of the matching entry. It is the responsibility of the calling application to free the memory allocated for dlEntry.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dlogInfo</code></td>
<td>Pointer to log information in dl_info</td>
</tr>
<tr>
<td><code>criteria</code></td>
<td>search criteria consisting of any of the following:</td>
</tr>
<tr>
<td><code>-d</code></td>
<td><code>device_name</code></td>
</tr>
<tr>
<td><code>-n</code></td>
<td><code>dlog_sequenceNumber</code></td>
</tr>
<tr>
<td><code>-L</code></td>
<td><code>deviceLocation</code></td>
</tr>
<tr>
<td><code>-t</code></td>
<td><code>entryType</code></td>
</tr>
<tr>
<td><code>-i</code></td>
<td><code>dlog_EntryIdentifier</code></td>
</tr>
<tr>
<td><code>-s</code></td>
<td><code>startTime</code> (format MMddhhmmyy)</td>
</tr>
<tr>
<td><code>-e</code></td>
<td><code>endTime</code> (format MMddhhmmyy)</td>
</tr>
<tr>
<td><code>filter</code></td>
<td>parsed search criteria</td>
</tr>
<tr>
<td><code>results</code></td>
<td>pointer to entry matching the search criteria</td>
</tr>
</tbody>
</table>

Call this function before calling `dlog_find_next`.

**Return Value**
Upon successful completion, a value >= 0 is returned. Otherwise, a value of -1 is returned.

**dlog_find_next**

**Purpose**
Finds the first diagnostic log entry that matches the specified criteria.

**Syntax**
```
#include <diag/diag_log.h>

int dlog_find_next(dl_info *dlogInfo, int index, dlSearch *filter, dlEntry **results)
```

**Description**
The `dlog_find_next` subroutine finds the first diagnostic log entry that matches the specified search filter. It allocates memory for the matching entry, and returns the array index of the matching entry. It is the responsibility of the calling application to free the memory allocated for dlEntry.
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dlogInfo</code></td>
<td>Pointer to log information in dl_info</td>
</tr>
<tr>
<td><code>index</code></td>
<td>Starting index</td>
</tr>
<tr>
<td><code>filter</code></td>
<td>Parsed search criteria</td>
</tr>
<tr>
<td><code>results</code></td>
<td>Pointer to entry matching the search criteria</td>
</tr>
</tbody>
</table>

Call this function after calling `dlog_find_first`.

Return Value

Upon successful completion, a value >= 0 is returned. Otherwise, a value of -1 is returned.

*dlog_find_sequence*

Purpose

Finds the diagnostic log entry that has the specified sequence number.

Syntax

```c
#include <diag/diag_log.h>

int dlog_find_sequence(dl_info *dlogInfo, uint seq, dlEntry **results)
```

Description

The `dlog_find_sequence` subroutine finds the diagnostic log entry with a specific diagnostic log sequence number. The matching entry will be in results and its index in the log array will be returned. It is the responsibility of the calling application to free the memory allocated for dlEntry. The results variable will be NULL if no match is found.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dlogInfo</code></td>
<td>Pointer to log information in dl_info</td>
</tr>
<tr>
<td><code>seq</code></td>
<td>Sequence number</td>
</tr>
<tr>
<td><code>results</code></td>
<td>Pointer to entry with the specified sequence number</td>
</tr>
</tbody>
</table>

Return Value

Upon successful completion, a value >= 0 is returned. Otherwise, a value of -1 is returned and results will be NULL.

*dlog_formatElogResults*

Purpose

Returns a formatted string of the diagnostic event log information.

Syntax

```c
#include <diag/diag_log.h>

char *dlog_formatElogResults(dlEntry *entry)
```

Description

The `dlog_formatElogResults` subroutine formats a diagnostic log entry for display in the error log with the `errpt` command. When a SRN is caused by an entry in the error log, the error log is updated with the diagnostic log entry's sequence number. When the error log is displayed the formatted string returned from this subroutine shows the diagnostic log information. It is up to the calling application to free the memory allocated for the return string.
The return string will look like the following:

- Diagnostic Log sequence number: sequence number
- Resource tested: resource name
- Resource Description: resource description
- Location: resource location
- SRN: SRN
- Description: Error Description
- Possible FRUs: List of possible FRUs

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dlogEntry</td>
<td>Pointer to diagnostic log entry</td>
</tr>
</tbody>
</table>

**Return Value**

Upon successful completion a NON-ZERO pointer is returned. Otherwise, a pointer to NULL is returned.

**dlog_freeEntry**

**Purpose**

Frees memory allocated for diagnostic log entry.

**Syntax**

```c
#include <diag/diag_log.h>

int dlog_freeEntry(int version, void *dlogEntry)
```

**Description**

The `dlog_freeEntry` subroutine frees all the memory allocated for the specified entry. The version determines which entry structure is being passed.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>Entry version (LATEST_ENTRY_VER is the latest version that corresponds to the dlEntry structure)</td>
</tr>
<tr>
<td>dlogEntry</td>
<td>Pointer to diagnostic log entry</td>
</tr>
</tbody>
</table>

**Return Value**

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned.

**dlog_open**

**Purpose**

Read an entry from the Diagnostic Event Log at the specified offset.

**Syntax**

```c
#include <diag/diag_log.h>

int dlog_open(char *pathname, dl_info **info)
```

**Description**

The `dlog_open` subroutine opens the specified log file for reading. If the pathname is NULL, then the default diagnostic log file will be used. This subroutine also allocates memory for the dl_info structure and initializes the structure.
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pathname</td>
<td>Name of log to open (if NULL, the default log is used)</td>
</tr>
<tr>
<td>info</td>
<td>Pointer to structure of format:</td>
</tr>
</tbody>
</table>

```c
typedef struct _log_info {
    int fd;           /* File descriptor */
    int lockId;       /* ODM Lock id */
    dl_att *dlAtt;    /* Pointer to log attributes */
    dl_einfo *dlArray; /* Pointer to log array */
} dl_info;
```

```c
typedef struct _log_einfo {
    int version;       /* Entry Version */
    char logType;       /* Log Type - I,S,N,E,X */
    unsigned int size;  /* Entry Size */
    unsigned int offset; /* Offset from the file's beginning */
} dl_einfo;
```

```c
typedef struct _log_att {
    int version;       /* Version */
    unsigned int numEntries; /* number of log entries */
    unsigned int lastIndex; /* index of latest entry */
    unsigned int nextSeqNum; /* sequence number of next log entry */
    unsigned int maxLogSize; /* maximum size of log */
    unsigned int arrayOffset; /* array offset */
    unsigned int wrapCount; /* number of times file has wrapped */
} dl_att;
```

Return Value
Upon successful completion, 0 is returned. Otherwise, a value of -1 is returned.

dlog_read

Purpose
Read an entry from the Diagnostic Event Log at the specified offset.

Syntax
```c
#include <diag/diag_log.h>

dlEntry *dlog_read(dl_info *dlogInfo, int index)
```

Description
The **dlog_read** subroutine will read a Diagnostic Event Log entry at the specified offset, which is determined from the index. It will return a pointer to a structure of format:

```c
typedef struct _logEntry {
    char type;           /* Log Type */
    char identifier[5];  /* Diagnostic Log identifier */
    unsigned int el_identifier; /* Error log identifier */
    int timestamp;
    unsigned int seqNum;  /* order in which event is logged */
    unsigned int el_seqNum; /* Error log sequence number */
    unsigned int session; /* Diag Session's PID */
    unsigned int testMode; /* Diagnostics test mode - hex value */
    resource_t *res_p;   /* Resource information */
    int resSize;         /* Size of resource info */
    void *errorInfo;     /* Error information */
    int errorSize;       /* Size of error info */
} dlEntry;
```
typedef struct resource {
    char name[NAME_SIZE];
    int locSize;
    char *location; /* Logical or Physical */
    short set;
    short msg;
    char catName[NAME_SIZE];
} resource_t;

Parameters

Parameter Description

dlogInfo Pointer to structure of format:

typedef struct _log_info {
    int fd; /* File descriptor */
    int lockId; /* ODM Lock id */
    dl_att *dlAtt;
    dl_einfo *dlArray;
} dl_info;

typedef struct _log_einfo {
    int version; /* Entry Version */
    char logType; /* Log Type - I,S,N,E,X */
    unsigned int size; /* Entry Size */
    unsigned int offset; /* Offset from the file's beginning */
} dl_einfo;

typedef struct _log_att {
    int version; /* Version */
    unsigned int numEntries; /* number of log entried */
    unsigned int lastIndex; /* index of latest entry */
    unsigned int nextSeqNum; /* sequence number of next log entry */
    unsigned int maxLogSize; /* maximum size of log */
    unsigned int arrayOffset; /* array offset */
    unsigned int wrapCount; /* number of times file has wrapped */
} dl_att;

index Index into Diagnostic Event log array for specific entry

Return Value
Upon successful completion, a pointer to dlEntry is returned. Otherwise, a value of NULL is returned.

dlog_same_elogId

Purpose
Determines if a diagnostic log entry has a specific error log identifier.

Syntax
#include <diag/diag_log.h>

int dlog_same_elogId(dlEntry *dlogEntry, uint el_identifier)

Description
The dlog_same_elogId subroutine determines if the specified entry has the same error log identifier as the given error log identifier.

Parameters

Parameter Description

dlogEntry Pointer to diagnostic log entry
el_identifier Error log identifier
Return Value
If the entry has the same error log identifier, a value of 1 is returned. Otherwise, a value of 0 is returned.

dlog_setEntryType

Purpose
Returns the entry type for a given diagnostic log identifier.

Syntax
```c
#include <diag/diag_log.h>
int dlog_setEntryType(char *id)
```

Description
The `dlog_setEntryType` subroutine returns an entry type for the specified entry identifier. The following entry types are defined:

<table>
<thead>
<tr>
<th>Entry Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INFO</td>
<td>Informational Type</td>
</tr>
<tr>
<td>NTF</td>
<td>No Trouble Found</td>
</tr>
<tr>
<td>ERR</td>
<td>Error</td>
</tr>
<tr>
<td>SRN</td>
<td>Srn Callout</td>
</tr>
<tr>
<td>EXER</td>
<td>Exerciser Error</td>
</tr>
<tr>
<td>SA</td>
<td>Service Aid</td>
</tr>
</tbody>
</table>

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>entry identifier</td>
</tr>
</tbody>
</table>

Return Value
Upon successful completion, the entry type is returned. Otherwise, a value of -1 is returned.

dlog_write

Purpose
Write a diagnostic event to the Diagnostic Event Log.

Syntax
```c
#include <diag/diag_log.h>
int dlog_write(diEntry *entry)
```

Description
The `dlog_write` subroutine writes a diagnostic event to the Diagnostic Event Log.
Parameters

Parameter | Description
--- | ---
entry | Pointer to a structure of type dlEntry, which is defined as follows:

```c
typedef struct _logEntry {
    char type; /* Log Type */
    char identifier[5]; /* Diagnostic log identifier */
    unsigned int el_identifier; /* Error log identifier */
    int timestamp;
    unsigned int seqNum; /* order in which event is logged */
    unsigned int el_seqNum; /* Error log sequence number */
    unsigned int session; /* Diag Session's PID */
    unsigned int testMode; /* Diagnostics test mode - hex value */
    resource_t *res_p; /* Resource information */
    int resSize; /* Size of resource info */
    void *errorInfo; /* Error information */
    int errorSize; /* Size of error info */
} dlEntry;
```

```c
typedef struct resource {
    char name[NAME_SIZE];
    int locSize;
    char *location;
    short set;
    short msg;
    char catName[NAME_SIZE];
} resource_t;
```

Return Value

The `dlog_write` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful</td>
</tr>
<tr>
<td>-1</td>
<td>Unsuccessful</td>
</tr>
<tr>
<td>ERROR_FS</td>
<td>Indicates the /var filesystem is full</td>
</tr>
</tbody>
</table>

**save_davars_ela**

Purpose

Formats SRN and create DAVars object with error log information.

Syntax

```c
#include <diag/diag_log.h>
int save_davars_ela(struct fru_bucket *frub,uint el_seq,uint el_id,uint errorCode)
```

Description

The `save_davars_ela` subroutine formats the SRN if the errorCode is 0, and create a DAVars object containing the error log information. The format of the DAVars object is:

DAVars:

dname = ResourceName
vname = "ErrorLogSRN_or_ErrorCode"
vtype = 0
vvalue = "ErrorlogIdentifier,ErrorlogSequenceNumber"
ivalue = 0

An example of a DAVars object is:
DAVars:
  dname = "hdisk0"
  vname = "ErrorLog689-130"
  vtype = 0
  vvalue = "1581762B,74"
  ivalue = 0

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*frub</td>
<td>Pointer to fru bucket</td>
</tr>
<tr>
<td>el_seq</td>
<td>Error log sequence number</td>
</tr>
<tr>
<td>el_id</td>
<td>Error log identifier</td>
</tr>
<tr>
<td>errorCode</td>
<td>Error code (if 0, format the SRN)</td>
</tr>
</tbody>
</table>

Return Value
The subroutine returns a value of 0 on success; a value of -1 on failure.

save_davars_mgoal_ela

Purpose
Create DAVars object with error log information for a menugoal.

Syntax
#include <diag/diag_log.h>
int save_davars_ela(char *dname, uint el_seq, uint el_id, uint menu_num)

Description
The save_davars_mgoal_ela subroutine creates a DAVars object containing the error log information for a menugoal. The format of the DAVars object is:

DAVars:
  dname = "ResourceName"
  vname = "ErrorMenuMenugoalNumber"
  vtype = 0
  vvalue = "ErrorlogIdentifier,ErrorlogSequenceNumber"
  ivalue = 0

An example of a DAVars object is:

  dname = "sysplanar0"
  vname = "ErrorMenu651202"
  vtype = 0
  vvalue = "56CDC3C8,22"
  ivalue = 0

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*dname</td>
<td>String containing the resource name that created the menugoal.</td>
</tr>
<tr>
<td>el_seq</td>
<td>Error log sequence number</td>
</tr>
<tr>
<td>el_id</td>
<td>Error log identifier</td>
</tr>
<tr>
<td>menu_num</td>
<td>Menugoal number</td>
</tr>
</tbody>
</table>

Return Value
The subroutine returns a value of 0 on success; a value of -1 on failure.
**copy_text**

**Purpose**
Format text to fit on line with a length of 74

**Syntax**
```
int copy_text( int string_length, char *buffer, char *text )
```

**Description**
The `copy_text` subroutine will take the text string and add \n so that the string can be displayed without wrapping.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string_length</td>
<td>Starting column for the formatted string</td>
</tr>
<tr>
<td>buffer</td>
<td>Formatted string</td>
</tr>
<tr>
<td>text</td>
<td>Unformatted string</td>
</tr>
</tbody>
</table>

**Return Value**
A value of 0 is returned.

**DA_SETRC_XXXXXX, DA_CHECKRC_XXXXXX, DA_EXIT**

**Purpose**
Processes Exit Status of Diagnostic Application (DA).

**Syntax**
```
#include <diag/diag_exit.h>

#define DA_SETRC_STATUS(VAL) da_exit_code.field.status = (VAL)
#define DA_SETRC_USER(VAL) da_exit_code.field.user = (VAL)
#define DA_SETRC_ERROR(VAL) da_exit_code.field.error = (VAL)
#define DA_SETRC_TESTS(VAL) da_exit_code.field.tests = (VAL)
#define DA_SETRC_MORE(VAL) da_exit_code.field.more = (VAL)
#define DA_CHECKRC_STATUS() da_exit_code.status
#define DA_CHECKRC_USER() da_exit_code.user
#define DA_CHECKRC_ERROR() da_exit_code.error
#define DA_CHECKRC_TESTS() da_exit_code.tests
#define DA_CHECKRC_MORE() da_exit_code.more
#define DA_EXIT() exit(*((char*) &da_exit_code) )
```

```
enum diag_enum_status {
    DA_STATUS_GOOD,
    DA_STATUS_BAD,
};
enum diag_enum_user {
    DA_USER_NOKEY,
    DA_USER_EXIT,
    DA_USER_QUIT,
};
```
enum diag_enum_error {
    DA_ERROR_NONE,
    /* No software errors were encountered */
    DA_ERROR_OPEN,
    /* The Device Driver failed to open */
    DA_ERROR_OTHER,
    /* Another software error was encountered */
};

enum diag_enum_tests {
    DA_TEST_NOTEST,
    /* No diagnostic tests were run */
    DA_TEST_FULL,
    /* The full tests were run */
    DA_TEST_SHR,
    /* The shared tests were run */
    DA_TEST_SUB,
    /* The sub tests were run */
};

enum diag_enum_more {
    DA_MORE_NOCONT,
    /* The problem has been isolated. */
    DA_MORE_CONT,
    /* The parent or sibling will be tested next */
};

typedef struct {
    unsigned status : 1;
    /* enum diag_enum_status */
    unsigned user : 2;
    /* enum diag_enum_user */
    unsigned error : 2;
    /* enum diag_enum_error */
    unsigned tests : 2;
    /* enum diag_enum_tests */
    unsigned more : 1;
    /* enum diag_enum_more */
} da_return_code_t;

extern da_returncode_t da_exit_code;

**Description**

The **DA_EXIT** macro is used to exit a DA. To set a value other than the default, the appropriate **DA_SETRC_XXXXX** macro must be called. To check the current value, use the appropriate **DA_CHECKRC_XXXXXX** macro.

The defaults settings are:

**DA_STATUS_GOOD**

**DA_USER_NOKEY**

**DA_ERROR_NONE**
DA_TEST_NOTEST
DA_MORE_NOCONT

Parameters
Takes no parameters.

Return Value
There is no return code.

Structure Deciphering
Following is a easy chart to use to deciphered the bit positions:

<table>
<thead>
<tr>
<th>Bit position</th>
</tr>
</thead>
<tbody>
<tr>
<td>128</td>
</tr>
<tr>
<td>64</td>
</tr>
<tr>
<td>32</td>
</tr>
<tr>
<td>16</td>
</tr>
<tr>
<td>8</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit position</th>
</tr>
</thead>
<tbody>
<tr>
<td>DA_MORE_NOCONT 0</td>
</tr>
<tr>
<td>DA_MORE_CONT 1</td>
</tr>
<tr>
<td>DA_TEST_NOTEST 0</td>
</tr>
<tr>
<td>DA_TEST_FULL 1</td>
</tr>
<tr>
<td>DA_TEST_SUB 2</td>
</tr>
<tr>
<td>DA_TEST_SHR 3</td>
</tr>
<tr>
<td>DA_ERROR_NONE 0</td>
</tr>
<tr>
<td>DA_ERROR_OPEN 1</td>
</tr>
<tr>
<td>DA_ERROR_OTHER 2</td>
</tr>
<tr>
<td>DA_USER_NOKEY 0</td>
</tr>
<tr>
<td>DA_USER_EXIT 1</td>
</tr>
<tr>
<td>DA_USER.Quit 2</td>
</tr>
<tr>
<td>DA_STATUS_GOOD 0</td>
</tr>
<tr>
<td>DA_STATUS_BAD 1</td>
</tr>
</tbody>
</table>

diag_asl_beep

Purpose
Rings the bell.

Syntax
#include <diag/diago.h>

long diag_asl_beep ( )

Description
The diag_asl_beep subroutine is used to ring the bell. Can be used to indicate that input is not valid.

Parameters
Takes no parameters.

Return Value
Upon successful completion, a value of 0 is returned.

diag_asl_execute

Purpose
Executes an application.
Syntax
#include <diag/diago.h>
long diag_asl_execute ( command, options, exit_status )
char *command;
char *options;
int *exit_status;

Description
The diag_asl_execute subroutine forks and executes an application while preserving the state of the ASL interface.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>command</td>
<td>Command or application to run.</td>
</tr>
<tr>
<td>options</td>
<td>Character array, starting with the command, followed by any command arguments, ending with a NULL.</td>
</tr>
<tr>
<td>exit_status</td>
<td>Exit status returned from the command.</td>
</tr>
</tbody>
</table>

Return Value
The following values are returned:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful return.</td>
</tr>
<tr>
<td>DIAG_ASL_FAIL</td>
<td>Error occurred.</td>
</tr>
</tbody>
</table>

diag_checkstop_eed

Purpose
Collect the checkstop Extended Error Data into a file.

Syntax
char *diag_checkstop_eed (char *dir)

Description
The diag_checkstop_eed subroutine collects Extended Error Data into a file in the directory given as input. The Extended Error Data file is the output of the snap -C command.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dir</td>
<td>Absolute path of the directory to create the EED file, maximum 200 characters.</td>
</tr>
</tbody>
</table>

Return Value
The diag_checkstop_eed subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>If error creating the EED file, otherwise, pointer to the absolute EED file name that will be in the form of dir/snapC.pax.Z, where dir is the directory passed as input.</td>
</tr>
</tbody>
</table>

diag_checkstop_event

Purpose
Determines if the diagnostic event was the result of a checkstop.
#include <diag/diag_log.h>

int diag_checkstop_event (query_output *entry, char *cs_file, unsigned int *cs_file_ts)

**Description**
The `diag_checkstop_event` subroutine will determine if the diagnostic event passed as input was caused by a checkstop. Since multiple errors can be logged following a checkstop, the checkstop scan file name and timestamp are returned to the calling routine for managing multiple reporting of the checkstop event.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>entry</td>
<td>The diagnostic event extracted from the diagnostic event log.</td>
</tr>
<tr>
<td>cs_file</td>
<td>The checkstop scanout file name.</td>
</tr>
<tr>
<td>cs_file_ts</td>
<td>The checkstop scanout integer timestamp.</td>
</tr>
</tbody>
</table>

**Return Value**
The `diag_checkstop_event` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>If the diagnostic event was from a checkstop.</td>
</tr>
<tr>
<td>0</td>
<td>Otherwise</td>
</tr>
</tbody>
</table>

### diag_cluster_support()

**Purpose**
Determines if the current system is part of a clustered environment.

**Syntax**

```c
int diag_cluster_support()
```

**Description**
The `diag_cluster_support()` routine determines if the cluster support software is installed to infer whether this system is part of a clustered environment.

**Parameters**
None.

**Return Value**

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Cluster support is not installed.</td>
</tr>
<tr>
<td>1</td>
<td>Cluster support is installed.</td>
</tr>
</tbody>
</table>

### diag_cpu2proc (int n)

**Purpose**
Convert logical CPU number to physical processor name.

**Syntax**

```c
char *diag_cpu2proc (n)
```

int n;
Description
The **diag_cpu2proc** routine is used to convert a logical CPU number to the physical processor name in ODM CuDv class.

**Note:** **init_dgodm** must be called before starting this subroutine.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>Integer that is the logical CPU number</td>
</tr>
</tbody>
</table>

**Return Value**

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>If error such as ODM error, or invalid logical CPU number.</td>
</tr>
<tr>
<td>procn</td>
<td>The name of the CuDv object for the physical processor</td>
</tr>
</tbody>
</table>

**diag_exec_source**

**Purpose**
Returns an indication of where diagnostics is being run from.

**Syntax**

```c
#include <diag/diago.h>

long diag_execute ( char *command, char *options, int *exit_status )
```

**Description**
The **diag_exec_source** determines where the diagnostics program is run from. If not from hard file, then `mount_point` contains the directory where the file system resides (CDRFS).

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mount_point</td>
<td>Character pointer to directory name where the file system resides.</td>
</tr>
</tbody>
</table>

**Return Value**
The **diag_exec_source** subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Running from hardfile.</td>
</tr>
<tr>
<td>1</td>
<td>Running from CD-ROM.</td>
</tr>
</tbody>
</table>

**diag_execute**

**Purpose**
Executes an application. Does not depend on ASL initialization.

**Syntax**

```c
#include <diag/diago.h>

long diag_execute ( char *command, char *options, int *exit_status )
```
Description
The `diag_asl_execute` subroutine forks and executes an application. This subroutine does not depend on ASL initialization, and it does not preserve the state of ASL.

Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>command</td>
<td>Command or application to run.</td>
</tr>
<tr>
<td>options</td>
<td>Character array, starting with the command, followed by any command arguments, ending with a NULL.</td>
</tr>
<tr>
<td>exit_status</td>
<td>Exit status returned from the command.</td>
</tr>
</tbody>
</table>

Return Value
The following values are returned:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful return.</td>
</tr>
<tr>
<td>-1</td>
<td>Error occurred.</td>
</tr>
</tbody>
</table>

`diag_general_eed`

Purpose
Collects the general Extended Error Data into a file.

Syntax
`char *diag_general_eed (char *dir)`

Description
The `diag_general_eed` subroutine collects Extended Error Data into a file in the directory given as input. The Extended Error Data file is the output of the `snap -H` command, with the addition of the output from the `diagrpt -a` and the `lsdev -C` commands.

Additional data can be collected and gathered in the EED by registering a collection application using a `PDiagAtt` ODM object class attribute `extend_gen_eed`. For more information, refer to `PDiagAtt`.

Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dir</td>
<td>Absolute path of the directory to create the EED file, maximum 200 characters.</td>
</tr>
</tbody>
</table>

Return Value
The `diag_general_eed` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>If error creating the EED file, otherwise, pointer to the absolute EED file name that will be in the form of <code>dir/snapH.pax.Z</code>, where <code>dir</code> is the directory passed as input.</td>
</tr>
</tbody>
</table>

`diag_get_cluster_ms ()`

Purpose
Retrieve the machine serial number of the cluster.

Syntax
`char *diag_get_cluster_ms()`
Description
The `diag_get_cluster_ms()` routine retrieves the machine serial number of the cluster by executing the `lscmtms` cluster software command. The results are parsed and the machine serial number is returned.

Return Value
NULL The machine serial number is not available.
string Value of the machine serial number.

diag_get_cluster_mt()

Purpose
Retrieves the machine type/model of the cluster.

Syntax
```c
char *diag_get_cluster_mt()
```

Description
The `diag_get_cluster_mt()` routine retrieves the machine type/model of the cluster by executing the `lscmtms` cluster software command. The results are parsed and the machine type/model is returned.

Parameters
None.

Return Value
NULL Machine type/model is not available.
string Value of machine type/model.

diag_get_fru_serial

Purpose
Gets the FRU serial number from the given FRU location code.

Syntax
```c
int diag_get_fru_serial(char *loc, char **fru_serial)
```

Description
The `diag_get_fru_serial` routine attempts to retrieve the FRU (field replaceable unit) serial number for a given physical location code.

Note: The calling routine must initialize and stop the Object Database Manager (ODM). It can use the diagnostic library routines, `init_dgodm()` and `term_dgodm()`, respectively.

Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>loc</td>
<td>Physical location of the FRU to return its FRU serial number.</td>
</tr>
<tr>
<td>fru_serial</td>
<td>Returns the FRU serial number if found, otherwise is set to NULL.</td>
</tr>
</tbody>
</table>
Return Value
The `diag_get_fru_serial` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>If there was an error retrieving the FRU serial number.</td>
</tr>
<tr>
<td>0</td>
<td>If the FRU serial number is not found.</td>
</tr>
<tr>
<td>1</td>
<td>If the FRU serial number was found, and <code>fru_serial</code> now points to the FRU serial number.</td>
</tr>
</tbody>
</table>

**dt**

**Purpose**
Writes diagnostic trace information to a file.

**Syntax**
```c
#include <diag/diag_trace.h>

void dt (dt_id, dt_type [,val, ...])
char *dt_id;
int dt_type;
```

**Description**
The `dt` subroutine allows trace information to be written to a file. If the file `/tmp/.DIAG_TRACE` exists, trace information is written to a file specified by the `dt_id` argument. The default is to overwrite existing trace information. To append to the trace file, `export DIAG_TRACE=APPEND`.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dt_id</code></td>
<td>Used to uniquely identify the trace file. The resulting trace file will be called <code>.dt.</code> followed by <code>dt_id</code> in the <code>/tmp</code> directory.</td>
</tr>
</tbody>
</table>
Parameter
dt_type

Description
The type of trace function to perform.

DT_TMI
Trace initialization for Diagnostic Applications (DA). Information from the TMInput structure will be written to the trace file.

DT_BEGIN
Trace initialization for Service Aids (SA).

DT_DEC
Trace an integer variable in decimal.

DT_MDEC
Trace multiple integer variables in decimal.

DT_HEX
Trace an integer variable in hexadecimal.

DT_MHEX
Trace multiple integer variables in hexadecimal.

DT_LDEC
Trace a long integer variable in decimal.

DT_MLDEC
Trace multiple long integer variables in decimal.

DT_LHEX
Trace a long integer variable in hexadecimal.

DT_MLHEX
Trace multiple long integer variables in hexadecimal.

DT_MSTR
Trace multiple string variables.

DT_MSG
Trace a simple message such as “hello.”

DT_BUFF
Trace a data buffer.

DT_SCSI_TUCB
Trace SCSI TUCB structure information.

DT_SCSI_TUCB_SD
Trace SCSI TUCB Sense Data information.

DT_END
Write “end of trace” identifier to the trace file.

val
Variable arguments which may include the number of multiple variables to trace, the trace labels, and the information to trace.

Return Value
There is no return code.

error_log_get

Purpose
Returns error-log entries.
Syntax
#include <diag/diag.h>

int error_log_get ( option, criteria, err_data )
int option;
char *criteria;
struct errdata *err_data;

Description
The error_log_get subroutine allows the Diagnostic Application (DA) to query the error log for entries.

Implementation Specifics
The NVRAMEL option is only supported on the POWER-based platform:

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>option</td>
<td>Describes the operation to be performed. The following values are defined:</td>
</tr>
<tr>
<td>INIT</td>
<td>Initializes error log retrieve.</td>
</tr>
<tr>
<td>SUBSEQ</td>
<td>Gets next error-log entry.</td>
</tr>
<tr>
<td>TERM</td>
<td>Ends error log retrieve.</td>
</tr>
<tr>
<td>NVRAMEL</td>
<td>Use the NVRAM error log as the source for the error log retrieve. Only the following members of struct errdata are available when the error log is obtained from NVRAM:</td>
</tr>
<tr>
<td></td>
<td>• time_stamp</td>
</tr>
<tr>
<td></td>
<td>• err_id</td>
</tr>
<tr>
<td></td>
<td>• resource</td>
</tr>
<tr>
<td></td>
<td>• detail_data_len</td>
</tr>
<tr>
<td></td>
<td>• detail_data</td>
</tr>
<tr>
<td>Note:</td>
<td>This option is only supported on the POWER-based platform.</td>
</tr>
<tr>
<td>INIT_IGNORE_LRA</td>
<td>Initializes error log retrieval and does not halt when a REPLACED_FRU entry is reached. Also, REPLACED_FRU entries can be returned in the err_data parameter. SUBSEQ calls following an INIT_IGNORE_LRA also do not halt when a REPLACED_FRU entry is reached.</td>
</tr>
<tr>
<td>INIT_NEW_ONLY</td>
<td>Initializes error log retrieval and returns the first error log entry matching the criteria that has not been previously analyzed by diagnostics.</td>
</tr>
<tr>
<td>SUBSEQ_NEW_ONLY</td>
<td>Gets the next error log entry matching the criteria that has not been previously analyzed by diagnostics.</td>
</tr>
<tr>
<td>criteria</td>
<td>Used with the INIT option to specify which device to obtain the error log data for and how far back to search. This parameter can be set to any valid option used by the errpt command.</td>
</tr>
<tr>
<td></td>
<td>When used with the NVRAMEL option, this can be either a list of resource names (with the -N switch) or an error ID (with the -j switch), but not both.</td>
</tr>
</tbody>
</table>
Parameter Description
struct errdata Data type that contains the following data filled in for use by the DA.
struct errdata {
    unsigned sequence; /* sequence number of entry */
    unsigned time_stamp; /* entry time stamp */
    unsigned err_id; /* error ID code */
    char *machine_id; /* machine ID */
    char *node_id; /* node */
    char *class; /* H=hardware, S=software */
    char *type; /* PERM,TEMP,PERF,PEND,UNKN */
    char *resource; /* Configured device name */
    char *vpd_data; /* VPD info */
    char *conn_where; /* connwhere field of CuDv */
    char *location; /* location field of CuDv */
    unsigned detail_data_len; /* length of detail data */
    char *detail_data; /* detail data */
}

Return Value

Return values are dependent on the option performed:

<table>
<thead>
<tr>
<th>Return Value</th>

</tr>
</tbody>
</table>
file_present

Purpose
Returns status indicating whether the file is present on the file system.

Syntax
```c
int file_present ( filename )
char *filename;
```

Description
The `file_present` subroutine determines the presence of a file.

Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename</td>
<td>Character pointer to full path name of file.</td>
</tr>
</tbody>
</table>

Return Value
The `file_present` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>File is not present.</td>
</tr>
<tr>
<td>1</td>
<td>File is present.</td>
</tr>
</tbody>
</table>

get_DApp

Purpose
Returns the `DApp` value associated with device as represented in the `PDiagAtt` object class.

Syntax
```c
char *get_DApp ( devicename, attribute )
char *devicename;
char *attribute;
```

Description
The `get_DApp` subroutine returns the `DApp` value from the `PDiagAtt` object class associated with the given device and attribute. Search criteria is in the following order:
1. `DClass` and `DSClass` and `DType` and attribute
2. `DClass` and `DSClass` and attribute
3. `DClass` and attribute

The calling application is responsible for freeing the storage allocated for the returned value.

Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>devicename</td>
<td>Character pointer to customized name of device.</td>
</tr>
<tr>
<td>attribute</td>
<td>Character pointer to attribute associated with device.</td>
</tr>
</tbody>
</table>

Return Value
The `get_DApp` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>char * NULL</td>
<td>Device and attribute is not found.</td>
</tr>
</tbody>
</table>
**getdainput, clrdainput**

**Purpose**
Gets and clears the input for the Diagnostic Application (DA).

**Syntax**
```c
#include <diag/tm_input.h>

int getdainput ( tm_input )
struct tm_input *tm_input;

int clrdainput ()
```

**Description**
The `getdainput` subroutine gets the input for the DA from the `TMInput` object class. The `clrdainput` subroutine clears the `TMInput` object class.

**Parameters**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tm_input</td>
<td>Pointer to the structure where the data should be written.</td>
</tr>
</tbody>
</table>

**Return Value**
Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned.

**getdavar, putdavar**

**Purpose**
Gets and puts persistent variables.

**Syntax**
```c
#include <diag/diag.h>

int getdavar ( dname, vname, vtype, val )
char *dname, *vname, *val;
unsigned short vtype;

int putdavar ( dname, vname, vtype, val )
char *dname, *vname, *val;
unsigned short vtype;
```

**Description**
The `getdavar` subroutine gets the persistent variable `vname` from the Diagnostic Application Variables object class. The `putdavar` subroutine is used to save the specified value.

**Parameters**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dname</td>
<td>Name of the device with which the variable is associated.</td>
</tr>
<tr>
<td>vname</td>
<td>Name of the variable.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>vtype</td>
<td>Type of the variable. The following values are defined:</td>
</tr>
</tbody>
</table>
|           | **DIAG_STRING**  
The variable should be treated as a character string. |
|           | **DIAG_INT**  
The variable should be treated as an integer. |
|           | **DIAG_SHORT**  
The variable should be treated as a short. |
| val       | Location where the variable should be written when the subroutine getdavar is called. Otherwise, val points to the value to be saved. |

**Return Value**
Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned.

**getELAdates**

**Purpose**
Return the start and end timestamp for retrieving error log entries.

**Syntax**
```c
char *getELAdates ( notRTOmode )
int notRTOmode;
```

**Description**
The getELAdates subroutine formats and returns a string containing the start and end timestamp that should be used for error log analysis. The end timestamp is the current date and time. The start timestamp is created using either the value specified by the Customized Diagnostic Attribute for run time options, or the value passed as a parameter. The string returned serves the same purpose as the date parameter of the TMInput object class.

**Note:** [init_dgodm] must be called before starting this subroutine.

**Parameters**

notRTOmode
Determines how the run time option value for the number of ELA days is used. If notRTOmode is 0, then the number of ELA days specified by the Customized Diagnostic Attribute for run time options is used to create the start timestamp. If notRTOmode is greater than 0, then the notRTOmode value is used as the number of ELA days when creating the start timestamp.

**Return Value**
The following string is returned:

```
-s MMddhhmmyy -e MMddhhmmyy
```

where:

- **dd** is the 2-digit value for day
- **hh** is the 2-digit value for the hour in 24-hour format
- **mm** is the 2-digit value for minutes
- **yy** is the 2-digit value for year
**has_diag_authority**

**Purpose**
Checks if a user has the proper authority to run diagnostics.

**Syntax**
```c
int has_diag_authority (chk_shutdown);
```

**Description**
The `has_diag_authority` subroutine checks if the user is authorized to run diagnostics.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>chk_shutdown</code></td>
<td>If TRUE, the subroutine checks to see if the user is authorized to shut down the system.</td>
</tr>
</tbody>
</table>

**Return Value**

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>User is not authorized to run diagnostics.</td>
</tr>
<tr>
<td>1</td>
<td>User is authorized to run diagnostics.</td>
</tr>
</tbody>
</table>

**ipl_mode**

**Purpose**
Returns the state of the diagnostic IPL mode.

**Syntax**
```c
#include <diag/diag.h>

int ipl_mode (source);
```

**Description**
The `ipl_mode` subroutine returns the state of the diagnostic IPL mode, and the IPL source.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>source</code></td>
<td>Set according to IPL source:</td>
</tr>
</tbody>
</table>

- If the value of the environment variable `DIAG_IPL_SOURCE` is `NULL` or `IPL_SOURCE_DISK` or `IPL_SOURCE_LAN`, then the value of `source` will be set to `DIAG_FALSE` (0).
- If the value of the environment variable `DIAG_IPL_SOURCE` is `IPL_SOURCE_CDROM` or `IPL_SOURCE_TAPE`, then the value of `source` will be set to `DIAG_TRUE` (1).

**Return Value**
The `ipl_mode` subroutine returns one of the following values:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>EXENV_IPL Diagnostics invoked during IPL</td>
</tr>
<tr>
<td>2</td>
<td>EXENV_STD Standalone Diagnostics, Online Service, or Online Maintenance</td>
</tr>
<tr>
<td>4</td>
<td>EXENV_CONC Online Concurrent Diagnostics</td>
</tr>
</tbody>
</table>

Chapter 3. Diagnostic Components  175
menugoal

Purpose
Concludes a Text Goal.

Syntax
int menugoal ( msg )
char *msg;

Description
The menugoal subroutine associates a menu goal with the device being tested. The TMInput object class identifies the device currently being tested.

Parameters

Parameter | Description
--- | ---
msg | Pointer to a text string that identifies a repair action intended for the customer, not a trained service representative. The msg parameter should contain a six-digit hex number (menu number) at the front of the buffer, followed by a space, and then the title line. Everything after the first carriage return is considered menu text.

Return Value
Upon successful completion, a value of 0 is returned. If the menugoal subroutine fails, then a value of -1 is returned.

schedule_ela

Purpose
Schedule ELA for a device.

Syntax
int schedule_ela ( device, minutes )
char *device;
int minutes;

Description
This routine is used to schedule Error Log Analysis (ELA) for a given device. Typically, this would be used by a Diagnostic Application to schedule ELA when processing indicates that an error log entry is expected and necessary for completing the diagnostic conclusion.

The scheduled time is the current time plus the number of minutes given as input. The number of minutes is limited to 24 hours. The scheduled ELA event, similar to using the diag -c -e -d device command, occurs one time only.

Parameters

Parameter | Description
--- | ---
device | The device name for which ELA should be run.
Example: sysplanar0

minutes | The number of minutes that is added to the current time to schedule ELA to run. Any value over 24 hours is truncated to a value less than 24 hours.
Example: 24 hours and 35 minutes (1475 minutes) is truncated to 35 minutes.

Return Value
There is no error return. Always returns 0.
Diagnostic Object Classes

The Diagnostic Package contains ODM object classes that are used extensively by the Diagnostic components. Some object classes store 'predefined' diagnostic information about the system and resources. Other object classes store 'customized' information that is built and used during runtime operation of diagnostics.

The following is a list of the Diagnostic ODM object classes:

- **PDiagRes** - Predefined Diagnostic Resource Object Class
- **PDiagAtt** - Predefined Diagnostic Attribute Device Object Class
- **PDiagTask** - Predefined Diagnostic Task Object Class
- **CDiagAtt** - Customized Diagnostic Attribute Object Class
- **TMInput** - Test Mode Input Object Class
- **MenuGoal** - Menu Goal Object Class
- **FRUB** - Fru Bucket Object Class
- **FRUs** - Fru Reporting Object Class
- **DAVars** - Diagnostic Application Variables Object Class
- **PDiagDev** - Predefined Diagnostic Devices Object Class
- **DSMOptions** - Diagnostic Supervisor Menu Options Object Class

### Predefined Diagnostic Resource Object Class

The **Predefined Diagnostic Resource** object class (**PDiagRes**) identifies the resources supported by diagnostics and provides additional information needed to test the resource.

The **PDiagRes** object class structure is defined as:

```c
class PDiagRes {
    char Uniquetype[48];
    short Ports;
    short PSet;
    short PreTest;
    char AttUniquetype[48];
    short SupTests;
    short Menu;
    short DNext;
    vchar DaName[255];
    char PkgBlock[5];
    vchar Enc1DaName[255];
    vchar SysxApp[255];
    vchar SupTasks[255];
    long FFC;
    short Fru;
    long TestSuiteId;
    long DiagEnvironment;
    vchar KernExt[255];
    char Version[5];
};
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Uniquetype</td>
<td>Predefined device “class/subclass/type.”</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>Ports</td>
<td>Indicates if the device will be represented in the Resource Selection menu by its children. The intent is to use device names that are well known to the user (for example, printers rather than serial ports). The values are as follows:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>DIAG_NO (0)</td>
<td>Child devices should not be defined.</td>
</tr>
<tr>
<td>DIAG_YES (1)</td>
<td>Child devices should be defined.</td>
</tr>
<tr>
<td></td>
<td>When determining whether a child device should be defined, consider whether the device is self-determining. Will the mkdev command be unsuccessful if the device is not really there?</td>
</tr>
<tr>
<td>PSet</td>
<td>Identifies the message set in either dcda.cat or the diagnostic application catalog file reserved for the device. If the Ports field is not equal to 0, the first message in the set describes the adapter port. This adapter text is used in place of the real device text so that the customers are not misled into thinking that they have devices that are not actually present. The additional messages are used for reason-code text, which the DAs name when reporting FRUs.</td>
</tr>
<tr>
<td></td>
<td>The diagnostic application catalog file should be used by all diagnostic applications integrated into the Diagnostic Package. This capability allows for greater flexibility in installing and maintaining the diagnostic code. To use this catalog file, set bit DIAG_DA_SRN in the Menu field.</td>
</tr>
<tr>
<td>PreTest</td>
<td>Indicates that the device should be tested before the system is brought up. Pretest occurs when the system is initial-program loaded with the key in service position. The keyboard device, native serial ports, and display adapters are normally pretested.</td>
</tr>
<tr>
<td>AttUniquetype</td>
<td>The device class/subclass/type of the child device to define when the Ports field is set. The device named should include a set of device drivers that contain support for diagnostics.</td>
</tr>
<tr>
<td>SupTests</td>
<td>Identifies the types of tests supported by the DA. See <a href="#">Staging the Impact of Diagnostics</a> for more information. More than one of the following types may be specified:</td>
</tr>
<tr>
<td>SUPTESTS_SHR (0x0001)</td>
<td>Shared tests are supported.</td>
</tr>
<tr>
<td>SUPTESTS_SUB (0x0002)</td>
<td>Sub-tests are supported.</td>
</tr>
<tr>
<td>SUPTESTS_FULL (0x0004)</td>
<td>Full-tests are supported.</td>
</tr>
<tr>
<td>SUPTESTS_MS1 (0x0008)</td>
<td>An optional procedure that determines why the device was not detected. This procedure is typically specified for devices that have external power supplies. This procedure is associated with the first selection at the Missing Resource menu.</td>
</tr>
<tr>
<td>SUPTESTS_MS2 (0x0010)</td>
<td>An optional procedure that performs device-specific actions when a device is removed. For example, the DA might notify a subsystem (LVM) that a physical resource (disk) has been removed. Or the DA might provide warning about deleting a device. If this procedure is not specified, the Diagnostic Controller deletes the device. If it is specified, the DA should delete the device. Devices are deleted by calling the device’s Undefine Method. This procedure is associated with the second selection at the Missing Resource menu.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Menu</strong></td>
<td>Identifies the diagnostic menus in which the device should be included. The values are as follows:</td>
</tr>
<tr>
<td></td>
<td><strong>DIAG_DTL (0x0001)</strong> The Diagnostic Test List menu.</td>
</tr>
<tr>
<td></td>
<td><strong>DIAG_NOTDLT (0x0002)</strong> Indicates that the device should not be allowed to be deleted from the Diagnostic Test List menu; for example, the VME adapters in the external display enclosure.</td>
</tr>
<tr>
<td></td>
<td><strong>DIAG_DS (0x0004)</strong> Indicates that the device should be included in the Diagnostic Selection menu.</td>
</tr>
<tr>
<td></td>
<td><strong>DIAG_CON (0x0008)</strong> Indicates that the device should be put in the Resource Selection menu if no children are attached; otherwise, the child device is put in the menu and the named device is not.</td>
</tr>
<tr>
<td></td>
<td><strong>DIAG_DA_SRN (0x0010)</strong> Indicates that the device’s SRN text resides in the diagnostic applications catalog file.</td>
</tr>
<tr>
<td><strong>DNext</strong></td>
<td>Indicates the resource to be tested next. The values are as follows:</td>
</tr>
<tr>
<td></td>
<td><strong>DIAG_PAR (0x0001)</strong> The parent resource.</td>
</tr>
<tr>
<td></td>
<td><strong>DIAG_SIB (0x0002)</strong> A sibling resource.</td>
</tr>
<tr>
<td><strong>DaName</strong></td>
<td>The name of the DA associated with the device.</td>
</tr>
<tr>
<td><strong>PkgBlock</strong></td>
<td>The block number that includes the DA associated with the device for the Removable Media Diagnostic package. This value should be an “S” if the DA is on a Supplemental Diskette, or a “3S” if the DA is a graphics adapter that can be used as a console device.</td>
</tr>
<tr>
<td><strong>EnclDaName</strong></td>
<td>This field names a DA that provides missing-device analysis for an enclosure that is not explicitly represented in the device configuration, but that needs to be processed before the missing device. Many enclosures have their own problem-determination procedures for checking cabling, power, idiot lights, and so on, and frequently, it is helpful to know if a sibling of the missing device in the same enclosure is available. The specification of a separate DA to missing-device diagnostics for devices not represented (for example, external enclosures or drawers) centralizes this logic in a single command instead of distributing it among each DA supporting a device that can operate in a bridge box or drawer. For most devices, this field is null. The Diagnostic Controller calls the <strong>EnclDaName</strong> field, if the user indicates that the device has not been moved or turned off. The <strong>EnclDaName</strong> field is called before <strong>DaName</strong>.</td>
</tr>
<tr>
<td><strong>SysxApp</strong></td>
<td>Identifies the application to invoke that performs a system exerciser function for this resource. While not currently used, this is a reserved field, and should be left blank.</td>
</tr>
<tr>
<td><strong>SupTasks</strong></td>
<td>Reserved. This field is retained for compatibility and should not be used. For more information, see <a href="#">Predefined Diagnostic Attribute Device</a>.</td>
</tr>
<tr>
<td><strong>FFC</strong></td>
<td>Failing Function Code for the resource. (may be used to override the <strong>PdDv led value</strong>).</td>
</tr>
<tr>
<td><strong>Fru</strong></td>
<td>Field Replaceable Unit indicator. (may be used to override the <strong>PdDv fru value</strong>):</td>
</tr>
<tr>
<td></td>
<td>0 No-Fru</td>
</tr>
<tr>
<td></td>
<td>1 Self-FRU</td>
</tr>
<tr>
<td></td>
<td>2 Parent-FRU</td>
</tr>
<tr>
<td></td>
<td>3 Hybrid - Could be integrated or nonintegrated device.</td>
</tr>
</tbody>
</table>
Parameter | Description
--- | ---
**TestSuiteId** | Bit mask indicating test suite this resource is a member of:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Resource</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Base system (planars, memory, etc.)</td>
</tr>
<tr>
<td>2</td>
<td>I/O Device (keyboard, mouse, etc.)</td>
</tr>
<tr>
<td>4</td>
<td>Asynchronous Device</td>
</tr>
<tr>
<td>8</td>
<td>Graphics</td>
</tr>
<tr>
<td>16</td>
<td>SCSI Adapters</td>
</tr>
<tr>
<td>32</td>
<td>Storage Device (disks, diskettes, tapes, etc.)</td>
</tr>
<tr>
<td>64</td>
<td>Commo</td>
</tr>
<tr>
<td>128</td>
<td>Multimedia</td>
</tr>
<tr>
<td>256</td>
<td>Miscellaneous Devices</td>
</tr>
</tbody>
</table>

**DiagEnvironment** | Bit mask indicating various test mode environments this resource is capable of running in:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Environment</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Supports Diagnostics in concurrent mode</td>
</tr>
<tr>
<td>2</td>
<td>Supports ELA</td>
</tr>
<tr>
<td>4</td>
<td>LFT Device (should not be run with X)</td>
</tr>
<tr>
<td>8</td>
<td>Group Member, set if this resource is part of a conglomerate group, such as memory, or SIMMS.</td>
</tr>
<tr>
<td>16</td>
<td>Resource supports ELA in concurrent mode only</td>
</tr>
<tr>
<td>32</td>
<td>Resource is not supported under WEBDIAG mode.</td>
</tr>
<tr>
<td>64</td>
<td>This object supports multiple resource types. The type for a given resource is found in the CuAt object attribute=aix-subtype. The value of the attribute is the type and is used to find the specific PDiagRes that supports the resource. A value of &quot;nodiag&quot; in the CuAt object indicates that the resource is not supported by diagnostics.</td>
</tr>
<tr>
<td>1024</td>
<td>The kernel extensions listed in KernExt are supported on the 64-bit kernel.</td>
</tr>
</tbody>
</table>

**KernExt** | `;` separated list of kernel extensions to load for this resource. Each kernel extension may be preceded by a platform type to indicate the platform that the kernel extension should be loaded on. For example, `chrp:device_kext, pdiagex` would indicate to always load `pdiagex`, and to conditionally load `device_kext` only on a ‘chrp’ platform. The platform name is derived as the output from the `lscfg | grep Architecture` command.

**Version** | Version change number for this resource stanza. This value should be 1.0.

---

Note: All values can be found in header files under `/usr/include/diag` directory.

**Predefined Diagnostic Attribute Device Object Class**

The **Predefined Diagnostic Attribute Device** object class (PDiagAtt) contains device-specific attributes for the DAs, diagnostic controller, and service aids to use.

The **PDiagAtt** object class structure is defined as:
```
class PDiagAtt {
    char DClass[16];
    char DSClass[16];
    char DType[16];
    char attribute[16];
};
```
 Parameter | Description
---|---
DClass | Predefined device class. Devices are uniquely identified by a combination of DClass, DSClass, and DType.
DSClass | Predefined device sub-class. Devices are uniquely identified by a combination of DClass, DSClass, and DType.
DType | Predefined device type.
attribute | 16-byte char field. The attribute value used by service aids to determine test mode for devices is test_mode. Uses value field.
value | 255-byte variable char field.
rep | 8-byte char field.
DApp | 255-byte variable char field.

Each field has specific meaning to each application that utilizes the Predefined Diagnostic Attribute Device object class (PDiagAtt).

EXAMPLES

- To specify the tasks that are supported by a resource, create a PDiagAtt stanza for the resource, indicating the supported tasks in the value field.

  PDiagAtt:
  ```
  DClass = "disk"
  DSClass = "scsi"
  DType = ""
  attribute = "SupTasks"
  value = "1,2,7,8,9,10,13,14,16,31,33"
  rep = "s"
  ```

  PDiagAtt:
  ```
  DClass = "disk"
  DSClass = "scsi"
  DType = "355mb"
  attribute = "SupTasks"
  value = "1,2,7,8,9,10,13,14,31,33"
  rep = "s"
  ```

  The search order performed by the Controller when determining the tasks a resource supports is as follows:
  - DClass, DSClass, DType
  - DClass, DSClass
  - DClass

  In the above example, if the disk type is 355mb, a match on the first call to search ODM is made; if not, a match will be made on the second call.

  **Note:** The 355mb does not have task id 16, which is microcode download.

- To specify the application for the Diagnostic Controller to execute for a specific resource that supports a task, then a stanza similar to the following is needed. This example tells the Controller to invoke ufd to start a format task on the selected resource that matches the diskette/siofd/fd criteria.

  PDiagAtt:
  ```
  DClass = "diskette"
  DSClass = "siofd"
  DType = "fd"
  attribute = "format"
  value = ""
  rep = "s"
  DApp = "ufd"
  ```

- The following stanza indicates the current release level of the Diagnostic Controller:
The **NoScreen** attribute is used by Display Test Pattern Service Aid to determine when a graphics adapter specific application should be used to display the screens for the service aid.

The service aid that uses this stanza is `/usr/lpp/diagnostics/bin/u5081`. The command that is built and executed is:

```
/usr/lpp/diagnostics/da/dsage <device name> -P
```

The **platform_task+** attribute allows third parties to add tasks to the Task List based on the hardware platform. The DApp field specifies the platform for the tasks in the Task List. The value field of the stanza contains a comma delimited list of the task IDs to be added.

In the example above, the tasks whose IDs are 101, 102 and 110 will be included in the task list on an ISA-bus based platform. Multiple PDiagAtt stanzas with the **platform_task+** attribute are allowed.

**Note:** The platform value for the DApp field is the string obtained by using the `lscfg | grep Architecture` command.

To register external notification programs with the Diagnostic Controller:

1. When the system is managed by a Hardware Management Console.
   ```plaintext
   PDiagAtt:
   DType = "<fileset nickname>
   DSClass = ""
   attribute = "notify_service"
   value = ""
   rep = "s"
   DClass = ""
   DApp = <complete path to external notification program>
   ```

2. When the system is not managed by a Hardware Management Console.
   ```plaintext
   PDiagAtt:
   DType = "<fileset nickname>
   DSClass = ""
   attribute = "notify_extern"
   value = ""
   rep = "s"
   DClass = ""
   DApp = <complete path to external notification program>
   ```
where <fileset nickname> is any 15 character or less string that represents which fileset ships this stanza. For example, fileset devices.chrp.base.diag might use a nickname DevChrBasDiag.

The application named in DApp will be executed with a diagnostics event log sequence number, or a list of sequence numbers.

- To register an application to gather additional Extended Error Data for external notification programs:

```
PDiagAtt:
  DType = <fileset nickname>
  DSClass = ""
  attribute = "extend_gen_eed"
  value = ""
  rep = "s"
  DCclass = ""
  Dapp = <complete path to the collection application>
```

where <fileset nickname> is any 15 character or less string that represents which fileset ships this stanza. For example, fileset devices.chrp.base.diag might use a nickname DevChrBasDiag.

The application named in DApp will be executed with a directory name as an argument. The application should put the collected data in files in the given directory. If the string in DApp contains -s, then the application will be executed with flags -s <error log sequence number> and -d <directory>.

### Predefined Diagnostic Task Object Class

The Predefined Diagnostic Task object class (PDiagTask) identifies the tasks supported by diagnostics and provides additional information needed to execute the task.

The PDiagTask object class structure is:

```c
class PDiagTask {
  long TaskId;
  long SetId;
  long MsgId;
  long Multisession;
  short Order;
  long ResourceFlag;
  long DiagEnvironment;
  short Builtin;
  vchar Action[255];
  vchar Catalog[255];
  vchar KernExt[255];
  short DescriptionSetId;
  short DescriptionMsgId;
  char PkgBlock[5];
};
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TaskId</td>
<td>Unique number identifying the task.</td>
</tr>
<tr>
<td>SetId</td>
<td>Catalog set number in either Dctrl.cat for the 'built-in' tasks, or in the catalog file specified for this task. The Setid and Msgid are used to display the task description on the Task Selection Menu.</td>
</tr>
<tr>
<td>MsgId</td>
<td>Catalog message number in either Dctrl.cat for the 'built-in' tasks, or in the catalog file specified for this task. The Setid and Msgid are used to display the task description on the Task Selection Menu.</td>
</tr>
<tr>
<td>Multisession</td>
<td>Flag indicating whether multiple instances of this task can be run simultaneously. While not currently used, this is a reserved field, and should be left blank.</td>
</tr>
<tr>
<td>Order</td>
<td>Order to display the tasks in the Task Selection Menu. Value of 0 implies no order required, and the task will be placed at the end. An order value greater than 900 implies that Task is a subtask.</td>
</tr>
</tbody>
</table>

Chapter 3. Diagnostic Components 183
<table>
<thead>
<tr>
<th>Parameter</th>

<td>',' separated list of kernel extensions to load for this task.</td>
</tr>
<tr>
<td>DescriptionSetId</td>
<td>Catalog set number of the help message text in either Dctrl.cat for the 'built-in' tasks, or in the catalog file specified for this task. The DescriptionSetId and DescriptionMsgId are used to display the help task description on the Task Selection Menu.</td>
</tr>
<tr>
<td>DescriptionMsgId</td>
<td>Catalog message number of the help message text in either Dctrl.cat for the 'built-in' tasks, or in the catalog file specified for this task. The DescriptionSetId and DescriptionMsgId are used to display the help task description on the Task Selection Menu.</td>
</tr>
</tbody>
</table>
Parameter Description
PkgBlock Block number that includes the task on the Removable Media Diagnostic package. This value should be an "S" if the task is on a Supplemental Media.

Customized Diagnostic Attribute Object Class

The Customized Diagnostic Attribute object class (CDiagAtt) contains customized entries for selected devices found in the current configuration, which is supported by diagnostics. The CDiagAtt object class indicates specialized diagnostic attribute status of the device. It is used to maintain diagnostic information about devices found in the current configuration across sessions.

The CDiagAtt object class structure is defined as:

class CDiagAtt {
    char name[16];
    char attribute[16];
    vchar value[255];
    char type[8];
    char rep[8];
};

Parameter Description
name Resource name as specified in CuDv.
attribute 16-byte char field. The attribute value used by the Controller to identify persistent state data for the device. Uses value field.
value 255-byte variable char field.
type 8-byte char field specifying data type.
rep 8-byte char field.

Examples:
- The Diagnostic Controller creates a CDiagAtt entry for each device that is tested periodically by the Diagnostic daemon. The format of the stanza looks like:

  CDiagAtt:
  name = "hdisk0" Resource to test
  attribute = "p_test_time" Attribute: periodic-test-time
  value = "0300" Test time (3AM)
  type = "T" Data type of 'text'
  rep = "s" 'String' representation

  CDiagAtt:
  name = "ent0" Resource name
  attribute = "p_test_time" Not tested
  value = "9999"
  type = "T"
  rep = "s"

- The Diagnostic Controller creates a CDiagAtt entry for each device that has been deleted from the resource list. The format of the stanza looks like:

  CDiagAtt:
  name = "mem0" Resource name
  attribute = "not_in_tst_list" Device has been deleted from the Resource List
  value = "1"
  type = "T"
  rep = "n"

Test Mode Input Object Class

The input parameters to the Diagnostic Application are stored in the TMInput object class. The subroutine getdainput should be used to retrieve the test mode input data values from this object class.
The **TMInput** object class structure is defined as:

```c
class TMInput {
    short exenv;
    short advanced;
    short system;
    short dmode;
    char date[80];
    short loopmode;
    short lcount;
    short lerrors;
    short console;
    char parent[16];
    char parentloc[16];
    char dname[16];
    char dnameloc[16];
    char child1[16];
    short state1;
    char childloc1[16];
    char child2[16];
    short state2;
    char childloc2[16];
    long pid;
    short cpuid;
};
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exenv</td>
<td>The execution environment. Possible values include the following:</td>
</tr>
<tr>
<td></td>
<td><strong>EXENV_IPL</strong></td>
</tr>
<tr>
<td></td>
<td>Diagnostics is being run in <strong>pre-test</strong> mode. Tests should not take longer than one-minute.</td>
</tr>
<tr>
<td></td>
<td><strong>EXENV_STD</strong></td>
</tr>
<tr>
<td></td>
<td>Standalone and Online Service diagnostics. The Service IPL was used to load the system. This can be accomplished either by initial program loading from disk or removable media. This mode also applies if the normal IPL was used to load the system and then maintenance mode was entered by issuing the command <code>shutdown -m</code>.</td>
</tr>
<tr>
<td></td>
<td><strong>EXENV_CONC</strong></td>
</tr>
<tr>
<td></td>
<td>Online Concurrent diagnostics. The Normal IPL was used to load the system.</td>
</tr>
<tr>

<td>Derived from the Diagnostic or Resource Selection menu. Possible values include the following:</td>
</tr>
<tr>
<td></td>
<td><strong>SYSTEM_TRUE</strong></td>
</tr>
<tr>
<td></td>
<td>System Checkout (All Resources) was chosen. The DAs perform noninteractive tests.</td>
</tr>
<tr>
<td></td>
<td><strong>SYSTEM_FALSE</strong></td>
</tr>
<tr>
<td></td>
<td>Option Checkout was chosen. The DAs perform interactive tests.</td>
</tr>
</tbody>
</table>
Parameter | Description
--- | ---
dmode | The diagnostic mode indicates the type of analysis that should be undertaken. Possible values include the following:

DMODE_ELA | Error-log analysis. No diagnostic tests are executed.

DMODE_MS1 | This procedure is started because the user indicated that the named device was not removed, moved, or turned off. This procedure should determine why the option was not detected. Generally, this type of analysis involves asking the user to check cables, power supplies, fans, panel lights, and so on. The device is not deleted from the configuration.

DMODE_MS2 | This procedure is started because the user indicated that the named device has been removed from the system and should be removed from the system configuration. This procedure should perform any unique "pseudo" device manipulation, notification, and so on. For example, when a physical disk is removed from the system, the LVM should be notified. The DA is responsible for deleting the device from the configuration. The Device’s Undefine Method is provided for this purpose.

DMODE_PD | Problem determination, including error-log analysis and diagnostics tests.

DMODE_REMIND | Diagnostic reminder, which defaults to running once a week, looks for deconfigured resources or other problems that have been previously reported, but have not been fixed.

DMODE_REPAIR | Repair checkout, which includes only diagnostics tests. The error log is not used because the user is attempting to verify new hardware.

date | The date from which the error log should be scanned. For the syntax used to describe the data, see the date command.

loopmode | The maintenance mode and service mode diagnostic package supports loop testing. All or part of the system can be tested multiple times. Possible values include the following:

LOOPMODE_NOTLM | Not loop mode. The default value for concurrent diagnostics.

LOOPMODE_ENTERLM | Entering loop mode. The DA can interact with the user to set up a test or to isolate a problem. The next time the DA is executed, it will be in loop mode.

LOOPMODE_INLM | In loop mode. No user interaction is allowed. The DA polls the keyboard. The tests should be stopped when the user presses Cancel.

LOOPMODE_EXITLM | The system is restored to its pretest state. The DA guides the user in the restoration of the system to its pretest state. For example, wrap plugs are removed and cables are replugged. No tests are executed.

lcount | Number of passes in loop mode that have been completed.
lerrors | Number of errors logged while in loop mode.

console | Diagnostic Controller queries the database to determine if the default console has been configured. Configuration states include:

CONSOLE_TRUE | A console is available.

CONSOLE_FALSE | No console is available, or no console output is desired. The LEDs are used to signal an error (if the platform supports LEDs).
Parameter | Description
---|---
parent | Name of the parent of dname.
parentloc | Location of parent. Format of string is “00-00-00-00”.
dname | Name of the device to be tested.
dnameloc | Location of dname. Format of string is “00-00-00-00”.
child1 | Name of the child device that has already been tested. Relevant for Option Checkout only.
childloc1 | Location of child1. Format of string is “00-00-00-00”.
state1 | State associated with child1. The resource states include:
  - **STATE_NOTEST**: The resource has *not* been tested.
  - **STATE_GOOD**: The resource passed its tests.
  - **STATE_BAD**: The resource failed its tests.
child2 | Name of another child device that has already been tested. Relevant for Option Checkout only.
childloc2 | Location of child2. The format of the string is “00-00-00-00”.
state2 | State associated with child2. The resource states include:
  - **STATE_NOTEST**: The resource has *not* been tested.
  - **STATE_GOOD**: The resource passed its tests.
  - **STATE_BAD**: The resource failed its tests.
pid | Process ID of the DA when started from the Controller.
cpuid | Logical processor number plus one which the DA when started from the Controller should bind itself to. While not currently used, this is a reserved field, and should be left blank.

All values can be found in `/usr/include/diag/tmdefs.h`.

### Menu Goal Object Class

The **Menu Goal** object class (`MenuGoal`) is used to store additional text information that the Diagnostic Application wants to pass back to the Diagnostic Controller. This text information is displayed to the user. This information is usually additional information that would be useful to the user concerning the state of the resource. One example would be that the Tape Drive requires cleaning.

All applications using the MenuGoal capability must use the `menugoal` diagnostic library subroutine.

The **MenuGoal** object class structure is defined as:

```c
class MenuGoal {
    char dname[16];
    longchar tbuffer1[1000];
    longchar tbuffer2[1000];
};
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dname</td>
<td>Resource name as specified in CuDV</td>
</tr>
<tr>
<td>tbuffer1</td>
<td>Buffer used to store 1000 bytes of text</td>
</tr>
<tr>
<td>tbuffer2</td>
<td>Buffer used to store 1000 bytes of text</td>
</tr>
</tbody>
</table>
FRU Bucket Object Class

The FRU Bucket Object Class (FRUB) is used to store failing replaceable unit information. This information is specified by the Diagnostic Application and passed back to the Diagnostic Controller after an error has been detected.

All applications using the FRU capability must use the addfrub diagnostic library subroutine.

The FRUB object class structure is defined as:

```c
class FRUB {
    char dname[16];
    short ftype;
    short sn;
    short rcode;
    short rmsg;
    char timestamp[80];
};
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dname</td>
<td>Names the device under test.</td>
</tr>
<tr>
<td>ftype</td>
<td>Indicates the type of FRU Bucket being added to the system. The following values are defined:</td>
</tr>
<tr>
<td></td>
<td>FRUB1 The FRUs include the resource that failed, its parent, and any cables needed to attach the resource to its parent.</td>
</tr>
<tr>
<td></td>
<td>FRUB2 This FRU Bucket is similar to FRU Bucket FRUB1, but does not include the parent resource.</td>
</tr>
<tr>
<td></td>
<td>FRUB_ENCLDA This FRU Bucket is used for missing devices in the I/O enclosure(s).</td>
</tr>
<tr>
<td>sn</td>
<td>Source number of the failure.</td>
</tr>
<tr>
<td>rcode</td>
<td>Reason code associated with the failure.</td>
</tr>
</tbody>
</table>

**Note:** A Service Request Number is formatted as follows:

SSS - RRR

where SSS is the sn and RRR is the rcode.

Some devices may use a different nomenclature for their service request numbers. For this special case, the sn parameter indicates how the rcode value should be formatted. If sn = 0, then rcode is interpreted as decimal. If sn = -1, then rcode is interpreted as a 4-digit hexadecimal number.

If sn = -2, then the object class DAVars is searched for an attribute of Error_code. This allows the displaying of eight-digit hex error codes. The diagnostic application is responsible for setting up a DAVars object similar to the following:

```c
DAVars:

dname: <device name under test>
vname: Error_code "Error_code is an ascii string"
vtype: DIAG_STRING "Literal value"
val: <8 digit hex character string>
```

See the getdavar/putdavar subroutine for more information.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rmsg</td>
<td>Message number of the text describing the reason code. The set number of the text is predefined by the PSet field in the Predefined Diagnostic Resources object class.</td>
</tr>
<tr>
<td>timestamp</td>
<td>Specifies the time the FRU bucket was added.</td>
</tr>
</tbody>
</table>
FRU Reporting Object Class

The FRU Reporting Object Class (FRUs) is used to store failing replaceable unit information. This information is specified by the Diagnostic Application and passed back to the Diagnostic Controller after an error has been detected.

All applications using the FRU capability must use the `addfrub` diagnostic library subroutine.

The FRUs object class structure is defined as:

```c
class FRUs {
    char dname[16];
    char fname[16];
    char floc[16];
    short ftype;
    short fmsg;
    short conf;
};
```

Parameter Description

- **dname**: Names the device under test.
- **fname**: Names the FRU.
- **floc**: Location icode for `fname`. Otherwise, they should be set to 0.
- **ftype**: Indicates the type of FRU Bucket being added to the system. The following values are defined:
  - **FRUB1**: The FRUs include the resource that failed, its parent, and any cables needed to attach the resource to its parent.
  - **FRUB2**: This FRU Bucket is similar to FRU Bucket FRUB1, but does not include the parent resource.
  - **FRUB.ENCLDA**: This FRU Bucket is used for missing devices in the I/O enclosure(s).
- **fmsg**: Message number of the text describing `fname`. The set number is predefined by the `PSet` descriptor in the Predefined Diagnostic Resources object class.
- **conf**: Indicates whether an FRU is valid. A value of 0 indicates an invalid FRU. No other FRUs are displayed once an invalid FRU is found in the FRU bucket.

However, if `fname` contains the string REF-CODE, then the `fmsg` and `conf` values are used to make the 8-digit ref code.

For AIX 4.3.2 and earlier versions, this field indicates the probability of failure associated with the named FRU.

Diagnostic Application Variables Object Class

The Diagnostic Application Variables Object Class (DAVars) is used to store run time information needed by the Diagnostic Application. This object class is used to store state variables to support Loop Testing.

All applications using the DAVars capability must use the `getdavar/putdavar` diagnostic library subroutine.

The DAVars object class structure is defined as:

```c
class DAVars {
    char dname[16];
    char vname[30];
    short vtype;
    char vvalue[30];
    long ivalue;
};
```
### Predefined Diagnostic Devices Object Class

The **Predefined Diagnostic Devices** object class (**PDiagDev**) identifies the resources supported by AIX 4.1 diagnostics and provides additional information needed to test the resource. This object class is recognized by the operating system for backlevel compatibility purposes. For development purposes, use **PDiagRes** instead.

The **PDiagDev** object class structure is defined as:

```c
class PDiagDev {
    char DType[16];
    char DSClass[16];
    short Ports;
    short PSet;
    short PreTest;
    char AttDType[16];
    char AttSClass[16];
    short Conc;
    short SupTests;
    short Menu;
    short DNext;
    vchar DaName[255];
    char Diskette[5];
    vchar Enc10DaName[255];
    short Sysxflg;
    char DClass[16];
};
```

<table>

</tbody>
</table>

*Menu*       | Same definition as **PDiagRes->Menu**.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

*DNext*      | Same definition as **PDiagRes->DNext**.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

*DaName*     | Same definition as **PDiagRes->DaName**.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

*Diskette*   | A diskette identification that includes the DA associated with the device for the Standalone Diagnostic package. This value should be an "S" if the DA is on a Supplemental Diskette, or a "3S" if the DA is a graphics adapter that can be used as a console device.                                                                                                                                                                                                                                    |

*EnclDaName* | Same definition as **PDiagRes->EnclDaName**.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
Parameter                  Description
SysxFlg                    Identifies the types of tests supported by the DA while running in the System Exerciser Environment. The System Exerciser Environment is not supported by version 4.2 of the diagnostic controller.

SYSX_NO                    Set if the DA should not be run by the System Exerciser.

SYSX_ALONE                 Set if the DA cannot be run with others with the same bit also set. This includes the diskette DAs that issue a reset to the adapter, which would cause problems if another diskette DA was running at the same time. Another example would be graphics-related devices such as the keyboard, mouse, tablet, dials, and LPFKeys.

SYSX_INTERACTION           Set if the DA can be run with media to be tested. This includes the diskette, tape and CD-ROM DAs. SYSX_INTERACTION was formerly SYSX_MEDIA.

SYSX_LONG                  Set if the DA runs for more than a minute or so. This bit can be used to determine how many times to run the other DAs if no long DAs are running. The current loop count for DAs that do not take long to run is 25 loops.

Diagnostic Supervisor Menu Options Object Class
The Diagnostic Supervisor Menu Options object class (DSMOptions) contains stanzas describing AIX 4.1 Diagnostic Service Aids. This object class is recognized by the operating system for backlevel compatibility purposes. For development purposes, use PDiagRes instead.

The DSMOptions object class structure is defined as:

class DSMOptions {
    char msgkey[4];
    vchar catalogue[255];
    short order;
    short setid;
    shortmsgid;
    vchar action[255];
    char Diskette[5];
};

Parameter                  Description
msgkey                     Key used by the Service Aid Utility Controller to identify this entry as a Service Aid. Must be set to “USM” for Service Aids.
catalogue                  Catalog name from which to extract the message for the Service Aid title and description.
order                      Order in which the messages should be appended to build the menu. The following values are defined:
                           0     Used by Third Party Service Aids. This causes the service aid to be appended to the end of the menu.
                           99    Only display this service aid if not running in an 8MB system.
setid                      Set number of the message.
msgid                      Message ID of the message.
action                     Command to start, if the user selects the specified option.
Diskette                   Indicates that the Service Aid is on a Supplemental Diskette, and what actions to take before processing the Service Aid. The following values are defined:
                           S     Supplemental Diskette.
                           100X  Indicates that all diskettes should be read in and processed before starting this service aid.
                           200X  Indicates that this service aid is only supported in Service Mode from hardfile.
Diagnostic Header Files

Several files are shipped to the `/usr/include/diag` directory for use with compiling diagnostic code. All variables used by this guide should be found in one of the diagnostic header files.

Diagnostic User Interface

The following sections describe how Diagnostic Applications and Diagnostic Tasks should use the interfaces provided in the Diagnostic Library to display the different screen types. The Diagnostic Subsystem supports various display environments. The menu interfaces are designed to be display environment independent, with the library routine(s) building the correct menu structures depending on the display environment.

Screen Types

The Diagnostic Subsystem uses six different screen types, displayed by four different functions:

<table>
<thead>
<tr>
<th>Screen Type</th>
<th>Diagnostic Applications</th>
<th>Diagnostic Tasks</th>
</tr>
</thead>
<tbody>
<tr>
<td>INFORMATIVE</td>
<td><code>diag_resource_screen</code></td>
<td><code>diag_task_screen</code></td>
</tr>
<tr>
<td>SINGLE SELECTION</td>
<td><code>diag_resource_screen</code></td>
<td><code>diag_task_screen</code></td>
</tr>
<tr>
<td>MULTIPLE SELECTION</td>
<td>n/a</td>
<td><code>diag_task_screen</code></td>
</tr>
<tr>
<td>DIALOG SELECTION</td>
<td>n/a</td>
<td><code>diag_task_screen</code></td>
</tr>
<tr>
<td>TRANSITIONAL</td>
<td><code>diag_resource_screen</code></td>
<td><code>diag_task_screen</code></td>
</tr>
<tr>
<td>POPUP</td>
<td><code>diag_popup</code></td>
<td><code>diag_popup</code></td>
</tr>
</tbody>
</table>

Screen Size Assumptions

In order for Diagnostics to run in a window, a minimum screen dimension of 24 lines by 80 columns is required.

INSTRUCTION LINE

The INSTRUCTION LINE will be added automatically depending on the screen type. The following table illustrates the messages used for the INSTRUCTION LINE.

<table>
<thead>
<tr>
<th>Screen Type</th>
<th>INSTRUCTION LINE</th>
</tr>
</thead>
<tbody>
<tr>
<td>INFORMATIVE</td>
<td>Use Enter to continue.</td>
</tr>
<tr>
<td>SINGLE SELECTION</td>
<td>Make selection, use Enter to continue.</td>
</tr>
<tr>
<td>MULTIPLE SELECTION</td>
<td>Make selection(s), use Commit to continue.</td>
</tr>
<tr>
<td>DIALOG SELECTION</td>
<td>Enter selection(s), use Commit to continue.</td>
</tr>
<tr>
<td>TRANSITIONAL</td>
<td>Please stand by.</td>
</tr>
<tr>
<td>POPUP</td>
<td>n/a</td>
</tr>
</tbody>
</table>

Diagnostic Applications

Diagnostic Applications should use one of the following screen types:

- INFORMATIVE
- SINGLE SELECTION
- TRANSITIONAL
The following template shows a sample screen that is used when running diagnostics on a resource. The DA would use the `diag_resource_screen` library function to display this screen.

The Title line is split between lines 1 and 2. The ACTION, TEST MODE, and the menu number go on the first line. ACTION is defined as one of the following:

- TESTING
- ANALYZING ERROR LOG
- ANALYZING POST RESULTS
- ANALYZING Firmware Status
- ANALYZING SUBSYSTEM STATUS
- ANALYZING CHECKSTOP STATUS

If the ACTION is TESTING, the TEST MODE will be displayed on the first line. TEST MODE is defined as:

- ADVANCED MODE
- LOOP MODE (Advanced Mode is always assumed if Looping.)

The TEST MODE field will be blank if running non-advanced mode diagnostics.

The Menu Number represented by xxxxxx, goes on the first line. The Resource Name and Location Code go on the second line.

The BODY of the menu can assume multiple personalities depending on the screen type. It includes all text of the menu, including the INSTRUCTION line. The BODY does not include the TITLE.

**INFORMATIVE Screen Type**

For an INFORMATIVE screen, the body consists of information describing the test and what it does. In the following example, lines 4 through 12 consist of the information about the test. Line 14 is the INSTRUCTION LINE, and is added automatically by the `diag_resource_screen` function.
SINGLE SELECTION Screen Type

For a SINGLE SELECTION screen, the body consists of results from a previous test that had run, and
asking the user if the results are accurate. The User selects a response, normally YES or NO, from a given
list. In the following example, lines 4 through 9 consist of the information about the test. Lines 13 and 14
provide the SELECTION lines. Line 11 is the INSTRUCTION LINE, and is added automatically by the
diag_resource_screen function.
TRANSITIONAL Screen Type

For a TRANSITIONAL screen, the body usually consists of a single INSTRUCTION line of Please stand by. This indicates that the test is currently processing some data. It is also used to indicate that looping is in progress, and shows the number of passes made plus the total number of errors encountered. User may press Cancel to stop the test. The following example shows a looping menu. Line 10 is the INSTRUCTION LINE, and is added automatically by the diag_resource_screen function. See also [Diagnostic Progress Indicators](#).

```
0123456789012345678901234567890123456789012345678901234567890123456789
1 2 3 4 5 6 7

17
18
19
20
21
22
23
24 F3=Cancel F10=Exit
```

POPUP Screen Type

For a POPUP screen, the application code should use the diag_popup library function call.

Diagnostic Tasks

Diagnostic Tasks are free to use any of the six supported screen types:

- INFORMATIVE
- SINGLE SELECTION
- MULTIPLE SELECTION
- DIALOG SELECTION
- TRANSITIONAL
- POPUP

The following template shows a sample screen that is used when running a task. The Task would use the diag_task_screen library function to display this screen.

The Title line is split between lines 1 and 2. Most all Task titles should fit on the first line, but the second line may be used for clarity or for translation reasons. The TITLE text should be all capitalized.

```
0123456789012345678901234567890123456789012345678901234567890123456789
1 2 3 4 5 6 7
1 TASK TITLE LINE 1
2 TASK TITLE LINE 2
3
```
The BODY of the menu can assume multiple personalities depending on the screen type. It includes all text of the menu, including the INSTRUCTION line. The BODY does not include the TITLE.

INFORMATIVE Screen Type
For an INFORMATIVE screen, the body consists of information describing the task and what it does. In the following example, lines 3 through 15 consist of the information about the task. Line 17 is the INSTRUCTION LINE, and Line 24 consists of the function keys available for this screen type. Both lines are added automatically by the `diag_task_screen` function.

**Note:** If the TITLE line consists of only one line, the text of the BODY will be adjusted up one line.

```plaintext
0123456789012345678901234567890123456789012345678901234567890123456789
--------------------------------------------------------------------------------
1 PERIODIC DIAGNOSTICS SERVICE AID 802150
2
3 This service aid is used to periodically test hardware resources and
4 monitor hardware errors in the error log.
5
6 A hardware resource can be chosen to be tested once a day, at a user
7 specified time of day. If the resource cannot be tested because it is
8 busy, error log analysis will be performed.
9 Hardware errors logged against a resource can also be monitored by enabling
10 Automatic Error Log Analysis. This will allow error log analysis to be
11 performed every time a hardware error is put into the error log.
12
13 If a problem is detected, a message will be posted to the system console
14 and a mail message sent to user(s) belonging to system group with information
15 about the failure such as Service Request Number.
16
17 Use Enter to continue.
18
19
20
21
22
23
24 [F1=Help] F3=Cancel F10=Exit Enter
--------------------------------------------------------------------------------
```
SINGLE SELECTION Screen Type

For a SINGLE SELECTION screen, the body consists of individual selectable items and possibly a short description. In the following example, lines 5 through 21 consist of the selectable items. This example illustrates six (6) selectable menu items. The indentions for the selectable item descriptions must be added when the message is built. Line 3 is the INSTRUCTION LINE, and is added automatically by the \texttt{diag\_task\_screen} function.

Any information about the selections may be added to the screen, and would appear after the TITLE line[1] and before the INSTRUCTION line[3].

\begin{verbatim}
0123456789012345678901234567890123456789012345678901234567890123456789
-------------------------------------------------------------------------------------------------
1 PERIODIC DIAGNOSTICS SERVICE AID 802151
2
3 Make selection, use Enter to continue.
4
5 Add a resource to the periodic test list
6 This selection allows a resource to be periodically tested.
7 Delete a resource from the periodic test list
8 This selection removes a resource from the list of periodically
9 tested resources.
10 Modify the time to test a resource
11 This selection allows the time of day to test a resource to be
12 changed.
13 Display the periodic test list
14 This selection displays all resources being tested periodically
15 by diagnostics.
16 Modify the error notification mailing list
17 This selection allows the mailing list for error notification
18 to be modified.
19 Disable Automatic Error Log Analysis
20 Automatic Error Log Analysis is currently enabled.
21 This selection stops the Automatic Error Log Analysis.
22
23
24 F1=Help F10=Exit F3=Previous Menu
-------------------------------------------------------------------------------------------------
23 F1=Help F4=List F10=Exit Enter
24 F3=Previous Menu
-------------------------------------------------------------------------------------------------
\end{verbatim}

MULTIPLE SELECTION Screen Type

For a MULTIPLE SELECTION screen, the body consists of individual selectable items and possibly a short description. In the following example, lines 10 through 12 consist of the selectable items. Line 8 is the INSTRUCTION LINE, and is added automatically by the \texttt{diag\_task\_screen} function.

Any information about the selections may be added to the screen, and would appear after the TITLE line[1] and before the INSTRUCTION line[8].

HELP text may be displayed any time the cursor is on line 10, 11, or 12 in the following example. Each selectable line may have associated HELP text.
DIALOG SELECTION Screen Type
For a DIALOG SELECTION screen, the body consists of individual items with a bracketed area to the right. This bracketed area allows data selections to be set for each individual item. In the following example, lines 10 and 11 consist of the items. Line 7 is the INSTRUCTION LINE, and is added automatically by the `diag_task_screen` function.

HELP text may be displayed any time the cursor is on line 10 or 11 in the following example. Each dialog line may have associated HELP text.

TRANSITIONAL Screen Type
For a TRANSITIONAL screen, the body consists of a single INSTRUCTION line of Please stand by. This indicates that the task is currently processing some data. Users may press Cancel to stop the task. The following example shows a task in progress menu. Line 6 consists of the INSTRUCTION LINE, and is automatically added by the `diag_task_screen` function. See also Diagnostic Progress Indicators.
Reading current error log.
Please stand by.

F3=Cancel    F10=Exit

-------------------------------

POPUP SCREEN TYPE

For a POPUP screen, the body consists normally of help text. It is used to help the user understand the current screen, or menu selection. In the following example, the popup appears in a windowed box near the bottom of the screen. No INSTRUCTION line is used. This screen is added by the \texttt{diag\_popup} function.

If the F1=Help key is selected, but there is no associated Help text associated with the current selection, then this key is returned to the calling application.

Move cursor to selection, then press Enter.

Chapter 3. Diagnostic Components  201
Diagnostic Progress Indicators

Diagnostic Progress Indicators are used to inform the user what is going on. The Progress Indicators appear as a popup box at the bottom of the screen during a Diagnostic Application TRANSITIONAL screen or a Diagnostic Task TRANSITIONAL screen display.

The Progress Indicators may be turned off by using the Run Time Options Task. This selection sets the diagnostic environment variable DIAG_NO_PROGRESS appropriately.

The following example shows a Diagnostic Application screen that is displaying a Progress indicator with the type of test unit being run.

```
<table>
<thead>
<tr>
<th>TEST MODE</th>
<th>LOOP MODE</th>
<th>935025</th>
</tr>
</thead>
<tbody>
<tr>
<td>fd0</td>
<td>00-00-00-00</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1 passes completed.</td>
<td>5 errors logged.</td>
<td></td>
</tr>
</tbody>
</table>
```

Please stand by.
These Progress Indicator messages must be kept short, one line, and under 30 characters. Note that the function key F10=Exit is overwritten by the Progress Indicator.

The `diag_progress` library function call is used for this Progress Indicator.

---

**Diagnostic Menu Examples**

### Diagnostic Operating Instructions Menu

**DIAGNOSTIC OPERATING INSTRUCTIONS**  
**VERSION X.X.X**  
**801001**

LICENSED MATERIAL and LICENSED INTERNAL CODE - PROPERTY OF IBM  
(C) COPYRIGHTS BY IBM AND BY OTHERS YYYY, YYYY.  
ALL RIGHTS RESERVED.

These programs contain diagnostics, service aids, and tasks for the system. These procedures should be used whenever problems with the system occur which have not been corrected by any software application procedures available.

In general, the procedures will run automatically. However, sometimes you will be required to select options, inform the system when to continue, and do simple tasks.

Several keys are used to control the procedures:
- The Enter key continues the procedure or performs an action.
- The Backspace key allows keying errors to be corrected.
- The cursor keys are used to select an option.

Press the F3 key to exit or press Enter to continue.

**Note:** The version number may vary depending on the version of diagnostics installed or the version the standalone diagnostics used.

### Function Selection Menu

**FUNCTION SELECTION**  
**801002**

Move cursor to selection, then press Enter.

- **Diagnostic Routines**  
  This selection will test the machine hardware. Wrap plugs and other advanced functions will not be used.

- **Advanced Diagnostics Routines**  
  This selection will test the machine hardware. Wrap plugs and other advanced functions will be used.

- **Task Selection (Diagnostics, Advanced Diagnostics, Service Aids, etc.)**  
  This selection will list the tasks supported by these procedures. Once a task is selected, a resource menu may be presented showing all resources supported by the task.

- **Resource Selection**  
  This selection will list the resources in the system that are supported by these procedures. Once a resource is selected, a task menu will be presented showing all tasks that can be run on the resource(s).

F1=Help    F10=Exit    F3=Previous Menu
Define Terminal Menu

DEFINE TERMINAL

The terminal is not properly initialized.
The following are some of the terminal types that are supported.

ibm3101  tvi912  vt330
ibm3151  tvi925  vt340
ibm3161  tvi920  wyse30
ibm3162  tvi950  wyse50
ibm3163  vs100  wyse60
ibm3164  vt100  wyse100
ibmpc  vt320  wyse350
lft  sun

NOTE: If you are using a Graphics Display, such as a
5081 or 6091 display, enter 'lft' as the
terminal type.

If the next screen is unreadable, press <CTRL> C.

Please enter a terminal type, or press Enter to return.

Missing Resource Selection Menu

MISSING RESOURCE

The list below shows all the missing resources. Make a selection,
then press Enter to process missing options resolutions.
To list all siblings of a resource, use 'List'.

Move cursor to selection, then press Enter.

System Verification
This selection will test the system, but will not analyze the error log. Use this option to verify that the machine is functioning correctly after completing a repair or an upgrade.

Problem Determination
This selection tests the system and analyzes the error log if one is available. Use this option when a problem is suspected on the machine.

Test Method Menu

Move cursor to selection, then press Enter.

- Run Test Once
- Run Test Multiple Times
  This selection should be used when a problem occurs intermittently.
  This selection will continue testing until 'Cancel' is pressed.

NOTE: After 'Cancel' is pressed, it may take some time before
the testing stops. The tests goes through a final phase
to return the resources to their original state.

No Trouble Found Menu

No trouble was found.

The resources tested were:
- proc0  00-00  Processor

Use Enter to continue.

Problem Report Menu

A PROBLEM WAS DETECTED ON Wed Jan  7 13:45:57 CST 1998

The Service Request Number(s)/Probable Cause or Cause(s):

816-185: I/O Planar - key lock failed.
  65%  OP Panel
  30%  Keylock
  5%   ioplanner0  00-00  I/O Planar
No trouble was found. However, the resource was not tested because the device driver indicated that the resource was in use.

The resource needed is
- hdisk0 00-04-00-1,0 670 MB SCSI Disk Drive

To test this resource, you can:
  Free this resource and continue testing.
  Shut down the system and run in maintenance mode.
  Run Diagnostics from the Diagnostic Standalone package.

Move cursor to selection, then press Enter.

Testing should stop.
The resource is now free and testing can continue.

From the list below, select a task by moving the cursor to the task and pressing 'Enter'.
To list the resources for the task highlighted, press 'List'.

[TOP]

From the list below, select a task by moving the cursor to the task and pressing 'Enter'.
To list the resources for the task highlighted, press 'List'.

Use the F4=List key to display all the resources supported by the selected Task.

**Run Time Options Menu**

Select values for the options below.
When finished, use 'Commit' to continue.

- Display Diagnostic Mode Selection Menus: [On] +
- Include Advanced Diagnostics: [Off] +
- Include Error Log Analysis: [Off] +
- Number of days used to search error log: [7] +
- Save changes to the database?: [NO] +
Chapter 4. Diagnostic Features

This chapter contains information on the various features that the Diagnostic Subsystem environment provides.

- **Missing Options Resolution**
- **Error Log Analysis**
- **Periodic Diagnostic Testing**
- **Automatic Error Log Analysis (DIAGELA)**
- **Loop Testing**

**Missing Options Resolution**

This section describes the Missing Options Resolution Procedure performed by Diagnostics when a change in the system configuration has been detected. This procedure can be run to clean up the system configuration database, or to determine why previously detected resources are no longer found by the operating system.

Each time the system boots from an installed hardfile, the device configuration database (CuDv) that is stored on the hardfile from the previous IPL is compared against the resources detected on the current IPL. Detectable resources that were found on the previous IPL but not the current IPL are marked as **MISSING**. Devices that were found on the current IPL, but not present in the previous IPL are marked as **NEW**.

The customized device entry CuDv chgstatus field is set to the changed status for each resource. These changed status values can be found in `/usr/include/sys/cfgdb.h` file.

When booting a system in normal mode, a message is written to the console if any devices have been detected as **MISSING**. This message states:

> A device that was previously detected could not be found.

> Run `diag -a` to update the system configuration.

The **diag -a** command can then be run to process the missing options resolution procedure.

When booting a system in online service mode, the missing options resolution procedure is run automatically if any missing devices were detected.

The following sections describe how the Diagnostic Controller presents information to the Diagnostic Applications that get invoked during Missing Options.

**Online Concurrent Diagnostics**

Missing Options Resolution procedure can be run in online concurrent mode by using the following command:

```
% diag -a // Runs in Customer Mode
OR
% diag -a -A // Runs in Advanced Mode
```

The first screen seen by the user is the **MISSING RESOURCE Menu** 801020.

The following **TMIInput** is an example of the input given to the Diagnostic Application when running the **diag -a** command.
The following TMInput is an example of the input given to the Diagnostic Application when running the diag -a -A command.

```
TMInput:
    exenv = 4 // Concurrent Environment
    advanced = 0 // Customer Mode
    system = 0 // Option Checkout
    dmode = 4 // System Verification
    date = "-s START -e NOW" // START = NOW - 24 hours.
    loopmode = 1 // Not in Loop Mode
    lcount = 0
    lerrors = 0
    console = 1 // Console Available
    parent = "parent0" // Parent of resource to test
    parentloc = "AB-CD" // Parent's Location Code
    dname = "resource0" // Name of resource to test
    dnameloc = "AB-CD" // Resource's Location Code
    child1 = "child0" // Missing Child of Resource
    childloc1 = "AB-CD" // Child's Location Code
    child2 = "" // Not in Loop Mode
    state1 = 3 // State of Child is MISSING
    state2 = 0
    childloc2 = ""
```

Online Service Diagnostics

Missing Options Resolution procedure is run automatically in online service mode when Diagnostics or Advanced Diagnostics selection is made from the FUNCTION SELECTION Menu.

When booting a system in online service mode, the OPERATING INSTRUCTIONS Menu and the FUNCTION SELECTION Menu are displayed in phase 1 by the service mode boot script. Once a selection is made, the selection is stored in `/etc/lpp/diagnostics/data/fastdiag` file, and phase 2 of the boot process commences.

The Diagnostic Application that gets called due to a missing child resource, after selecting Diagnostic Routines from the FUNCTION SELECTION menu, gets a TMInput shown below:

```
TMInput:
    exenv = 2 // Standalone Environment
    advanced = 0 // Customer Mode
    system = 0 // Option Checkout
    dmode = 4 // System Verification
    date = "-s START -e NOW" // START = NOW - 24 hours.
    loopmode = 1 // Not in Loop Mode
    lcount = 0
```
The Diagnostic Application that gets called due to a missing child resource, after selecting Advanced Diagnostic Routines from the FUNCTION SELECTION menu, gets a **TMInput** shown below:

```
TMIinput:
exenv  = 2  // Standalone Environment
advanced = 1  // Advanced Mode
system   = 0  // Option Checkout
dmode   = 4  // System Verification
date    = "-s START -e NOW" // START = NOW - 24 hours.
loopmode= 1  // Not in Loop Mode
lcount  = 0
lerrors = 0
console = 1  // Console Available
parent  = "parent0"  // Parent of resource to test
parentloc = "AB-CD"  // Parent's Location Code
dname   = "resource0"  // Name of resource to test
dnameloc = "AB-CD"  // Resource's Location Code
child1 = "child0"  // Missing Child of Resource
state1 = 3  // State of Child is MISSING
childloc1 = "AB-CD"  // Child's Location Code
child2 = ""  // Missing child resource
state2 = 0
childloc2 = ""
```

**Standalone Diagnostics (POWER-based only)**

Missing Options Resolution procedure is not run during Standalone Diagnostics. The reason for this is that there is no previous configuration database for the Diagnostic Controller to compare against with the new devices detected at boot time.

Therefore, only the NEW RESOURCES menu is seen during Standalone Diagnostics. This menu presents a list of all the resources found in the system at the time the Standalone Diagnostics were booted.

The user is given a list of choices to make during this time. If the system contains ISA adapters, then these adapters will not appear in the list. ISA adapters are not detectable, therefore an option is presented to the user to help in the configuration of these adapters.

**Missing Options Procedure Steps**

The following describes the steps performed by the Diagnostic Controller when running the Missing Options Procedure.

1. The Diagnostic Controller keeps a sorted list of all resources found in the system as represented by the **Customized Device** object class. This list is walked finding all resources that are tagged as **MISSING**.

2. Present the Missing Device menu for all **MISSING** devices. This menu lists each missing device with any children devices indented a few spaces. Missing Options Resolution Procedure can only be performed on the missing devices that do not have a parent also missing. See **MISSING RESOURCE Menu** for an example of this menu.
3. After selection of a device, present the Missing Device Resolution menu. The menu asks the user if the device was moved, removed, or turned off. The following selections may be chosen:
   a. The resource has NOT been removed from the system, moved to another location or address, or turned off.
      This selection will determine why the resource was not detected.
      1) Test the path to the missing device.
      2) If a device in the path is defective, then skip to the next "missing" device in the list that is not dependent on the one just named. Note that the defective device in the path has been added to the FRU Bucket object class by the Diagnostic Application (DA).
      3) Return to the step where the missing device menu was presented.
      4) If an EnclDAName DA is named, call it.
      5) If a problem was detected, skip to the next missing device in the list that has a different parent, and return to the step where the Missing Device menu was presented.
      6) If a missing device procedure was specified (suptests & SUPTESTS_MS1), then call it. Note that the DA should conclude that there is a problem.
      7) Skip to the next missing device in the list that is not dependent on the current missing device.
      8) Return to the step where the Missing Device menu was presented.
      9) If a missing device procedure was not specified, then add the device to the FRU Bucket object class by the addfrub subroutine. The default information is obtained from the Predefined Device object class.
   b. The resource has been removed from the system and should be removed from the system configuration.
      1) If the DA for the missing device supports the Missing Device Procedure 2 (suptests==SUPTESTS_MS2), then call the DA. The Diagnostic Controller does not automatically delete the device from the system configuration.
      2) Otherwise, flag the device to be deleted.
   c. The resource has been moved to another location and should be removed from the system configuration.
      1) Display a list of the new devices that are of the same type so that the user can identify where the missing device was moved. This list should contain a default selection for "Not Listed" in the event that the device was not detected in its new location, in which case a default service request number (SRN) should be generated.
      2) Assuming the user identified a new location:
         a) If the missing device has children which are non-detectable:
            • Present a menu to the user asking if the children should be reconfigured to the new device. The menu should contain a single selection for all of the devices and additional selections for the individual devices.
            • When a device is chosen, the parent field needs to be changed and the device configured. The mkdev command is used to configure the device.
         b) Delete the missing device and any children that have not been reconfigured.
   d. The resource has been turned off and should be removed from the system configuration.
      1) Flag the device to be removed from the configuration database.
   e. The resource has been turned off but should remain in the system configuration.
      1) Do nothing.
4. Once all the missing devices have been processed through one of the selections above, then perform the following:
   a. Report any problems found.
   b. Delete the devices that were previously flagged to be deleted.
c. If a new resource has been added, then display a list of the new devices. Ask the user if the list is correct.
   1) If Yes, then exit.
   2) If No, display predefined SRN indicating some new devices were not detected. Exit.

Error Log Analysis

Error log analysis does not test the resource. Instead this method searches the operating system error log for an entry (or entries) related to the resource. If an entry is found, then an analysis is performed on the error that was logged, and a determination is made by the Diagnostic Application as to whether the resource should be called out as being bad.

Error log analysis is performed via different methods with the Diagnostic Subsystem. One method is that error log analysis is performed automatically whenever a permanent hardware error is logged to the operating system error log. This method is called [Automatic Error Log Analysis (DIAGELA)](Automatic Error Log Analysis (DIAGELA)).

A second method can be set up to run diagnostics automatically at a pre-set time of the day. This method is referred to as [Periodic Diagnostics](Periodic Diagnostics).

A third method can be run directly from the command line by using the `-e` flag with the `diag` command.

A fourth method is invoked automatically whenever diagnostics is ran in Problem Determination Mode after first starting diagnostics. This method is described below.

Running Problem Determination Mode in Diagnostics

If Problem Determination mode is selected upon entering diagnostics the first time, the Diagnostic Controller searches the operating system error log for any Permanent Hardware errors. If any errors were logged within the last 24 hours, the appropriate Diagnostic Application is called to analyze the error log. If a problem is suspected due to an error logged, a Problem Report screen will be presented to the user. If no problem is found, then the Resource Selection menu is displayed.

Periodic Diagnostics

Periodic testing of the disk drives and battery are enabled by default on systems that support these tests. The disk diagnostics perform disk error log analysis on all disks. The battery test checks the real-time clock and NV-RAM battery.

Periodic diagnostics are performed in different ways, depending on the diagnostic version. Use the [Periodic Diagnostics](Periodic Diagnostics) task to change the test times or to add other resources to the list.

Processors that are dynamically removed from the system will also be removed from the periodic test list. Processors that are dynamically added are automatically added to the periodic test list.

AIX Version 3

A root crontab entry performs periodic testing of the disk drives and battery. One entry in the root crontab table runs disk diagnostics at 3:01 a.m. each day. Another entry tests the battery at 4:01 a.m. each day. These tests can be disabled by editing the root crontab file. The disk entry is `/etc/lpp/diagnostics/bin/run_ela` while the battery entry is `/etc/lpp/diagnostics/bin/test_batt`.

Problems are reported by a message to the system console and logged in the error log. Diagnostics must be run for a SRN to be reported.

Running diagnostics in this mode is similar to using the `diag -c -e -d device` command.
AIX Version 4

The Periodic Diagnostic Service Aid controls periodic testing. The Periodic Diagnostic Service Aid allows error log analysis to be run on a hardware resource once a day. The battery and all disk drives are enabled to run. Error log analysis is performed on all the disk drives at 3:00 a.m. each day.

Other devices as necessary can be added into the Periodic Diagnostic Device list to run at various other times, if desired.

Problems are reported by a message to the system console and a mail message to all users of the system group. The message contains the SRN.

Running diagnostics in this mode for planar and memory tests is similar to using the `diag -c -d device` command. All other devices are invoked with the `-e` flag appended.

AIX 5L

Beginning with AIX 5.2, Periodic Diagnostics supports only processors. Periodic Diagnostics automatically analyzes the error log and reports the errors. Periodic Diagnostics supports processor diagnostics on systems that own the processor. However, some hardware platforms own the processors and provide testing instead of AIX, so Periodic Diagnostics on those processors is not supported. Errors on the processors owned by the platform are logged by the platform and analyzed by automatic error log analysis.

Support is determined at run time from the characteristics of the hardware configuration. Periodic Diagnostics determines it is not supported when processors do not have physical location codes, which are created by platform firmware and passed to the operating system.

If processors have a physical location code, then the partition owns the processor and Periodic Diagnostics is supported. If there is no physical location code for a processor, it is a shared or virtual processor and Periodic Diagnostics is not supported.

Technical Description

The Diagnostic daemon `diagd` executes once the `bos.diag` diagnostic package is installed. The `diagd` looks for customized entries in `CDiagAtt` odm database to determine which devices to run at which times. (For AIX 4.1, the database is `CDiagDev`.) The database is built when diagnostics are run or the Periodic Diagnostic Service Aid is run to change run times for devices. If the database has no entries (for example, when diagnostics have never been run), then default times are given to the ioplanar battery test and disk drives. The following is an example of `CDiagAtt` entries.

```
CDiagAtt->attribute = p_test_time
CDiagAtt->value = 9999 Do not test
     = 0400 Test at 4AM
```

The `diagd` sets a timer to wake up at the next scheduled time to run. Once `diagd` wakes up, the script `/usr/lpp/diagnostics/bin/diagela` is executed with the `-t` flag.

`diagela` checks the `PDiagAtt->test_mode` bit for the device to determine whether that device should be tested in this mode. If the bit is not set, `diagela` does not test the device. If the bit is set, diagnostics are run on the device with the `-e` (ELA) flag set.

Platform firmware, rather than Periodic Diagnostics, is used to test memory and processors on some systems. AIX still reports errors on these resources, but firmware does the actual testing. If the `diagd` determines that there are no resources to test periodically, it will terminate.
Limitation

IBM System p5 does not support AIX processor diagnostics and Periodic Diagnostics on in any version of AIX.

Automatic Error Log Analysis (DIAGELA)

Automatic Error Log Analysis (diagela) provides the capability to do error log analysis whenever a permanent hardware error is logged. Whenever a permanent hardware resource error is logged and the diagela program is enabled, the diagela program is invoked. Automatic Error Log Analysis is enabled by default on all platforms.

The diagela program determines whether the error should be analyzed by the diagnostics. If the error should be analyzed, a diagnostic application will be invoked and the error will be analyzed. No testing is done. If the diagnostics determines that the error requires a service action, it sends a message to your console and to all system groups. The message contains the SRN, or a corrective action.

Running diagnostics in this mode is similar to using the diag -c -e -d device command.

Notification can also be customized by adding a stanza to the PDiagAtt object class. The following example illustrates how a customer's program can be invoked in place of the normal mail message:

```plaintext
PDiagAtt:

DClass = ""
DSClass = ""
DType = ""
attribute = "diag_notify"
value = "/usr/bin/customer_notify_program $1 $2 $3 $4 $5 $6"
DApp = ""
```

If DClass, DSClass, and DType are blank, then the customer_notify_program will apply for ALL devices. Filling in the DClass, DSClass, and DType with specifics will cause the customer_notify_program to be invoked only for that device type.

Once the above stanza is added to the ODM data base, problems will be displayed on the system console and the program specified in the value field of the diag_notify pre-defined attribute will be invoked. The following keywords will be expanded automatically as arguments to the notify program:

```plaintext
$1 the keyword diag_notify
$2 the resource name that reported the problem
$3 the Service Request Number
$4 the device type
$5 the error label from the error log entry
$6 the process id of the diagnostic session reporting the problem
```

In the case where no diagnostic program is found to analyze the error log entry, or analysis is done but no error was reported, a separate program can be specified to be invoked. This is accomplished by adding a stanza to the PDiagAtt object class with an attribute = diag_analyze. The following example illustrates how a customer's program can be invoked for this condition:

```plaintext
PDiagAtt:

DClass = ""
DSClass = ""
DType = ""
attribute = "diag_analyze"
value = "/usr/bin/customer_analyzer_program $1 $2 $3 $4 $5"
reps = "$5"
DApp = ""
```
If $DClass$, $DSClass$, and $DType$ are blank, then the **customer_analyzer_program** will apply for ALL devices. Filling in the $DClass$, $DSClass$, and $DType$ with specifics will cause the **customer_analyzer_program** to be invoked only for that device type.

Once the above stanza is added to the ODM data base, the program specified will be invoked if there is no diagnostic program specified for the error, or if analysis was done, but no error found. The following keywords will be expanded automatically as arguments to the analyzer program:

$1$ the keyword **diag_analyze**
$2$ the resource name that reported the problem
$3$ the error label from the error log entry if invoked for ELA, or the keyword **PERIODIC** if invoked for Periodic Diagnostics, or the keyword **REMINDER** if invoked for providing a Diagnostic Reminder
$4$ the device type
$5$ the keyword: **no_trouble_found**, if analyzer was run, but no trouble was found; or **no_analyzer**, if analyzer not available.

To activate the Automatic Error Log Analysis feature, log in as root and type the following command:

```
/usr/lpp/diagnostics/bin/diagela ENABLE
```

To disable the Automatic Error Log Analysis feature, log in as root and type the following command:

```
/usr/lpp/diagnostics/bin/diagela DISABLE
```

**Diagela** can also be enabled and disabled using the **Periodic Diagnostic** Service Aid.

---

**Loop Testing**

Loop testing is the testing of a resource or resources multiple times under program control. The looping is controlled by the Diagnostic Controller. Loop testing is only supported when running in maintenance mode or service mode, and **Advanced Diagnostic Routines** have been chosen.

The user indicates that loop testing is desired at the **Test Method** menu. The rule associated with loop testing is that user interaction is only allowed on the first and last pass.

The diagnostic applications get notification that loop mode has been invoked by obtaining the value of `loopmode` in the **TMInput** object class. The following actions should be taken by the DA when `loopmode` has the following values:

**LOOPMODE_ENTERLM**

The Diagnostic Application should perform any tests as usual, plus perform Error Log Analysis if running in Problem Determination mode.

**LOOPMODE_INLM**

The Diagnostic Application should perform any tests as usual, and not Error Log Analysis.

**LOOPMODE_EXITLM**

The Diagnostic Application should not perform any tests, nor perform Error Log Analysis. Instead cleanup procedures should be invoked to remove wrap plugs, etc, before exiting.
Chapter 5. Diagnostic Packaging

This chapter contains information on the various components that make up the Diagnostic Subsystem environment.

- **Hardfile Packaging**
- **CDROM Packaging**
- **Diagnostic Supplemental Media**

**Hardfile Packaging**

This chapter contains information on how the various diagnostic files are packaged. These packages are used by the install process to load diagnostics on the hardfile.

**Software Packages and Filesets**

Diagnostics is packaged into separate software packages and filesets. The base diagnostics support is contained in package `bos.diag`. The individual device support is packaged in separate `devices.[type].deviceid` packages.

The `bos.diag` package is split into three distinct filesets:

<table>
<thead>
<tr>
<th>Fileset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bos.diag.rte</code></td>
<td>Contains the Controller and other base diagnostic code.</td>
</tr>
<tr>
<td><code>bos.diag.util</code></td>
<td>Contains the Service Aids and Tasks.</td>
</tr>
<tr>
<td><code>bos.diag.com</code></td>
<td>Contains the diagnostic libraries, kernel extensions, and development header files.</td>
</tr>
</tbody>
</table>

The `devices.[type].deviceid` packages are split into various distinct filesets. `type` usually signifies a bus type, or device class of devices. `deviceid` usually signifies a unique identifier for the device. For example:

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>devices.mca.8d77.rte</code></td>
<td>Contains the device driver and configuration methods for the Micro Channel 8-bit SCSI I/O Controller.</td>
</tr>
<tr>
<td><code>devices.mca.8d77.diag</code></td>
<td>Contains the Diagnostic Application and default catalog file for the device.</td>
</tr>
</tbody>
</table>

These packages/filesets are normally installed to a hardfile with the `installp` command.

**Directory Structure Organization**

The following shows the directory structures used by the Diagnostic Subsystem. New files created for diagnostic purposes should follow the same convention.

- `/etc/lpp/diagnostics/data` - Contains files that are created (Read/Write) by the diagnostics programs. Examples are the diagnostic report files created by the Diagnostic Controller.
- `/usr/lpp/diagnostics/bin` - Contains the Diagnostic Controller, and Service Aids/Tasks.
- `/usr/lpp/diagnostics/da` - Contains the Diagnostic Applications.
- `/usr/lpp/diagnostics/catalog` - Contains the default (English) catalog files used by all Diagnostic programs.
- `/usr/lpp/diagnostics/slih` - Contains the Second Level Interrupt Handlers used by the Test Units.
- `/usr/lpp/diagnostics/lib` - Contains the loadable Test Unit Libraries.

**Note:** The translated diagnostic catalog files are in `/usr/lib/nls/msg/[LANG]` directories.
CDROM Packaging (POWER-based only)

The Standalone Diagnostic CDROM contains all programs and applications necessary to run Diagnostics. This includes the latest version of the operating system, device drivers, device configuration methods, diagnostic applications, and ODM stanzas.

Device support that is not on the Diagnostic CDROM must be supported by Diagnostic Supplemental Media.

Starting with AIX 4.1, the Rock Ridge-based CDROM File System was used for the Diagnostic CDROM. The Rock Ridge CDROM File System supports directory levels deeper than 8, mixed-case file names and a file structure similar to operating system file systems.

Diagnostic Supplemental Media

A Diagnostic Supplemental Media contains all the necessary diagnostic programs and files required to test a particular resource when used with the Standalone Diagnostic CDROM. The supplemental is normally released and shipped with the resource as indicated on the diskette label.

The Process Supplemental Media task processes the diagnostic supplemental media.

The following topics describe the Diagnostic Supplemental Media and the contents in more detail.

- Diagnostic Supplemental Diskette Contents
- Example ODM Stanzas
- Example diagstartS Script File
- Example diagstart3S Script File
- Diagnostic Supplemental Diskette Labels

Diagnostic Supplemental Diskette Contents

A Diagnostic Supplemental Diskette must contain all files required to configure and test a device. Three special files, diagstartS, diagS.dep, and diagcleanupS, are required by the Standalone Diagnostic Package to maintain the software on the diskette. The diskette must be written in cpio format. Use the C36 block option on the cpio command to create the diskette. The following list describes each required file:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>etc/diagstartS</td>
<td>Shell script (with execute permission) to add the object class stanzas to the database, configure the devices, and so on. See the example diagstartS shell script file. This file must be the first file on diskette.</td>
</tr>
<tr>
<td>etc/diagS.dep</td>
<td>Dependency file. This file is a list of all files on the diskette. Each file must be listed with its full path name.</td>
</tr>
<tr>
<td>etc/diagcleanupS</td>
<td>Cleanup script file. This script should perform any cleanup necessary after the supplemental has been processed and run; for example, restoring the ODM database to its original condition if the supplemental changed some of the original values.</td>
</tr>
<tr>
<td>etc/stanzas/device .add</td>
<td>Stanza file for the device. The stanzas must include the PdDv, PdCh, PdAt, and PDiagRes information required for the device. Note: Use PDiagRes if the device is only supported on AIX 4.2 and later. If the supplemental can be used on a pre-AIX 4.2 system, then PDiagDev must be used.</td>
</tr>
<tr>
<td>usr/lib/drivers/deviceedd</td>
<td>Device driver for the device. The deviceedd variable should be the name of the device driver.</td>
</tr>
</tbody>
</table>
File
usr/lib/methods/devicecfgmethod and usr/lib/methods/deviceunconfigmethod

Methods necessary to define, configure, undefine, and unconfigure the device. The names must be the same referenced by the PdDv method objects. Do not include any methods that are already part of the operating system. Include only the unique methods used by this device.

usr/lib/methods/devicedesc.cat

Device description catalog file devicedesc.cat should be the name of the catalog file referenced by the PdDv catalog object. The device description file should contain the description of the device shown when using the lsdev or lscfg command.

usr/lpp/diagnostics/da/ddevice

Diagnostic Application (DA) for the device. The ddevice variable should be the name of the DA, which is the same name referenced by the PDiagRes DaName object.

usr/lpp/diagnostics/catalog/default/ddevice.cat

DA message catalog for the device. The DA menus are included in this file.

This message catalog file also contains FRU information. The set number used must be the same number referenced by the PDiagRes PSet object.

Note: If the supplemental diskette being developed is for a graphics adapter that can be used as a console device, then the suffix 3S should be used instead of S. For example, the file etc/diagstartS should be etc/diagstart3S, etc/diagS.dep should be etc/diag3S.dep, and etc/diagcleanupS should be etc/diagcleanup3S.

usr/lpp/diagnostics/slih/device_slih
usr/lpp/diagnostics/lib/lib_device

Second Level Interrupt Handler for the device.
Device Test Unit loadable library.

Example ODM Stanzas

PdDv:

type = xyz
subclass = mca
class = adapter
catalog = xyz.cat
setno = 1
msgno = 1
Define = /usr/lib/methods/definexyz
Configure = /usr/lib/methods/cfgxyz
Undefine = /usr/lib/methods/udefinexyz
Unconfigure = /usr/lib/methods/ucfgxyz
led = 0x902
fru = 1 1 if device is FRU
     2 if parent is FRU

PDiagRes:

UniqueType = adapter/mca/xyz
PSet = 1
DaName = dxyz
PkgBlock = S
Menu = 21
DNext = 1
SupTests = 7

For a description of all fields in PDiagRes, refer to Predefined Diagnostic Resource Object Class

/usr/lib/methods/xyz.cat:

else
   echo > /tmp/3S       # flag that indicates diskette read.
   exit 0

Diagnostic Supplemental Diskette Label
Each Diagnostic Supplemental Diskette must have a label. The label should state the lowest version of the operating system that the diskette supports. For instance, if the supplemental diskette was initially built on AIX 4.1, then the version of the diskette should say 4.1.
Chapter 6. Diagnostic Debugging Hints

This section has hints on how to debug applications in a Diagnostic environment. The following areas are covered:

- **Debugging Hints for Diagnostic Applications**
- **Debugging Hints for Diagnostic Kernel Extension**
- **Diagnostic Patch Diskette Procedure**

### Debugging Hints for Diagnostic Applications

The Diagnostic Controller uses the process ID (PID) of the DA to determine which TMInput object class entry to use for the DA during execution. To debug the DA, run the following:

```bash
export DIAG_DEBUG=1
```

- Run diagnostics as usual against your resource once.
  ```bash
  odmget TMInput > /tmp/tminput.add # save off contents of TMInput.
  ```
- Edit the `/tmp/tminput.add` file and set the `pid` field to 0.
  ```bash
  odmdelete -o TMInput # delete what is currently in TMInput.
  odmadd /tmp/tminput.add # add new contents of TMInput.
  ```
- Execute the code debugger against the DA.

If the Diagnostic Application uses a kernel extension or Second Level Interrupt Handler, you may have to perform the following before trying to load and debug the DA.

- Load the kernel extension. This can be done by running diagnostics once on the device, and then exiting. The Controller will normally load any kernel extensions needed by the DA. When exiting Diagnostics, the Controller does not unload the extensions, so it should still be loaded during the debugging,
- Export the diagnostic environment variable `DIAGX_SLIH_DIR` to `/usr/lpp/diagnostics/slih`.

### Debugging Hints for Diagnostic Kernel Extension

- **Starting Trace for Diagnostic Kernel Extension**
- **Running Trace for Diagnostic Kernel Extension in the Background**
- **Finding the Right Address**
- **Looking at an Illegal Trap**

#### Starting Trace for Diagnostic Kernel Extension

The Diagnostic Controller loads the Kernel Extensions for each device that requires it. This is specified by the `PDiagRes->KernExt ODM stanza` for the device. If using `DIAGEX` or `PDIAGEX`, there is a trace hook built in for debugging purposes.

To use this trace hook, you first must make sure that the `trace` command is installed. This command is part of the `bos.sysmgt.trace` fileset.

To run trace, perform the following:

```bash
trace -j 355 # Invoke trace
trcon # Start trace
!diag -d "device_name" # Run diagnostics against the device
trcoff # Stop trace
quit # Quit
```

To generate a trace file, perform the following:
This trace file will contain all the steps performed by the diagnostic kernel extension. To understand the tags, you must use the source code.

**Running Trace for Diagnostic Kernel Extension in the Background**

The Diagnostic Controller loads the Kernel Extensions for each device that requires it. This is specified by the PDiagRes->KernExt ODM stanza for the device. If you are using DIAGEX or PDIAGEX, there is a trace hook built in for debugging purposes.

To use this trace hook, first make sure that the trace command is installed. This command is part of the bos.sysmgt.trace filesset.

To run trace in the background, enter:
```
trace -a -j 355 -L < length of file > -o < filename >
```

The -L flag overrides the default trace log file size of 1 MB with the value stated. Specifying a file size of zero sets the trace log file size to the default size. The -o flag outputs trace data to a specific trace log file.

To generate a trace file, enter:
```
trcrpt < filename > < output filename >
```

This trace file will contain all the steps performed by the diagnostic kernel extension. To understand the tags, you must use the source code.

**Note:** You can only have one trace running at a time.

To stop a trace, enter:
```
trcstop
```

**Finding the Right Address**

**Note:** The following examples are based on a particular debugger. The concepts shown can be applied using the debugger available to you.

While in the Kernel Debugger, there is a structure that can be searched that gives the address of the trace buffer and first device handle. For DIAGEX, this structure is `diag_cntl`. For PDIAGEX, it is `pdiag_cntl`. Use the `map` command to get the address of the structure.

For instance, for PDIAGEX:

1. `>0> map pdiag_cntl`
   `pdiag_cntl:0x0123F220, type:CSECT Definition`

2. Use that address and display 100 words:
   ```
   >0> d 123F220 100
   0123F220  FFFFFF  FFFFFF  05C8A400  00000764  ..................d
   0123F230  64677874  72616365  544F5021  21212121  dgxtraceTOP!!!.
   0123F240  72775F61  00000004  00000000  00000000  rw_a............
   0123F250  67697042  00000000  2FF3B270  2FF3B270  gipB......./..p
   0123F260  67697064  000000C0  00000000  00000000  gipd............
   0123F270  67697045  00000000  00000000  gipE....=............
   0123F280  67697042  00000001  00000001  rw_b............
   0123F290  72775F62  00000000  00000000  00000000  rw_E............
   0123F2A0  52656445  00000000  20001111  00000000  RedE..........
   0123F2B0  57727442  00000000  00000001  00000000  WrtB............
   0123F2C0  5772742B  14000000  00000000  00000000  Wrt+............
   0123F2D0  5772742B  00000000  00000007  00000000  Wrt+...{....
   0123F2E0  72775F45  00000000  00000000  00000000  rw_B............
   ```
The first and second words, FFFFFFFF, are locks. Ignore them.

The third word (in bold) is a pointer to the linked list of device handles.

The fourth word is the start of the internal trace table.

dgxtraceTOP! defines the TOP of the trace table.

dgxtraceBOT! defines the end of the trace table.

3. The current pointer can be found by searching from this point for dgxtraceCUR!:

Work backwards from this point to see exactly what events have taken place to this point.

4. As far as the device handles are concerned, display 100 words to see the data associated with the device at that address (the third word from 2.b above):

The 8th word is a pointer to the next device in the linked list. In this case the 8th word is 00000000, indicating this is the only device.

Looking at an Illegal Trap

In some instances, an Illegal Trap Instruction may occur if some application unloads their SLIH or kernel extension, without having previously unpinned its memory. This can also happen if the Diagnostic Kernel Extension close routine is not called on exit.

If this happens when the debugger is enabled, a screen similar to the following may appear. The appearance of ff_free in the dump is the indicator that an application did not unpin some code before unloading.

The address passed to ff_free is in (r29) or r30. Use the (s)creen command to trace back until you see a familiar function name. In the following example, the SLIH mps_interrupt was indicated.

1. Trap Occurs:

   GP0  00000000 2FF3B188 00192DF0 00000016 00008000 00000000 2FF3B400

Diagnostic Patch Diskette Procedure

Patch diskettes can be made to help in the debug of problems that occur when running diagnostics from the Diagnostic CDROM. Three types of diskettes can be used:

- **Diagnostic Configuration Diskette**
- **Diagnostic Patch Diskette**
- **Diagnostic Debug Diskette**

The Diagnostic Patch Diskette purpose is to allow file replacement from diskette, overriding the file(s) on the CDROM. All diskettes are in backup/restore format. The Diagnostic Debug diskette can be combined with the other two to allow command line debugging as well as file replacement.
Diagnostic Configuration Diskette
The Diagnostic Configuration diskette has two main purposes.

The first purpose of the Diagnostic Configuration diskette is to allow the refresh rate of the graphics adapter to be set to a different value than the default. The default value is 60Hz. If the graphics display’s refresh rate is 77 Hz, then set the refresh rate to 77.

The second purpose of the Diagnostic Configuration diskette is to allow a terminal attached to any RS232 or RS422 adapter to be selected as a console device. The default device is a RS232 tty attached to the first standard serial port(S1).

Each of these can be accomplished by using the Create Customized Configuration Diskette Task.

A valid Diagnostic Configuration Diskette contains the following files:
- ./signature
- ./CONSDEF
- ./REFRESH

The .signature file contains a single line describing the diskette purpose. For this diskette, the description should be /etc/diagconf.

Diagnostic Patch Diskette
The Diagnostic Patch diskette is used to patch failing applications until a new release of the Diagnostic CDROM is available. This diskette may also be used in development to help in the debug of why a particular application is failing.

A valid Diagnostic Patch Diskette contains the following files:
- ./signature
- ./etc/diagpatch
- ./etc/[applications]

The .signature file contains a single line describing the diskette purpose. For this diskette, the description should be /etc/diagpatch. The /etc/diagpatch file is a Korn shell script file that is used to remove the application first from the RAM file system, then links the new application to the old one. The /etc/diagpatch file must be executable. Following is an example:

```
#!/bin/ksh
####
begin diagpatch
#
Files
to
be
replaced
on
the
RAM
file
system
must
first
be
removed,
then
linked
from
/etc
to
/usr/lpp/....[or
correct
location]
###

Replacing
a
diagnostic
application
rm/usr/lpp/diagnostics/da/dxspa
ln -s /etc/dxspa /usr/lpp/diagnostics/da/dxspa
```

Diagnostic Debug Diskette
A valid Diagnostic Debug Diskette contains the following files:
- ./signature
- ./etc/NOKEYPOS

The .signature file contains a single line describing the diskette purpose. For this diskette, the description could be either /etc/diagpatch or /etc/diagconf. The script file does not need to be present if files are not being replaced.
The `/etc/NOKEYPOS` file is a zero length file.

**Note:** This function can be combined with either the Patch or Configuration diskette by simply adding the `/etc/NOKEYPOS` file to either diskette.
Chapter 7. Code Examples

This chapter contains various sample 'C' programming code for both the Application Test Unit and Diagnostic Application code. These samples are meant for review to understand the concepts and library routines used. None of these will compile clean. They are included here as reference only.

- Example {DEVICE}_ERR_DETAIL.H: TU Specific Outputs
- Example {DEVICE}_INPUT_PARAMS.H: TU Specific Inputs
- Example TU Local Header File
- Example TU execu Function
- Example TU Open/Close Device Interface
- Example TU Makefiles
- Example C Source File for TU Interrupt Handler
- Example TU Interrupt Handler Makefile
- Example Diagnostic Application
- Example Diagnostic Application Message File

Example {DEVICE}_ERR_DETAIL.H: TU Specific Outputs

```c
/*
 * COMPONENT_NAME: TU_DEVICE
 *  
 * FUNCTIONS: SAMPLE Header file for TU Error Detail (OUTPUT)
 *  
 */

#ifndef h_device_err_detail
#define h_device_err_detail

// ERROR_DETAILS structure and related definitions follow.
// These structures are used to provide detailed error information
// for some of the errors that are detected by the test units.
// Whether the detailed error is available for a particular TU and error
// code is documented in the TU Component Interface Specification, and
// the actual source files where that error code is defined.

typedef struct {

/*  
* NAME : tu_test  
*  
* FUNCTION : Executes test units and reports FRUs to the controller  
* if a failure is found.
EXECUTION ENVIRONMENT:

Called by the main program to execute test units.
Call external routine exeetu to actually execute the test units.
Call external routine diag_sasl_read to get user's input to screen
  e.g. Cancel or Exit.
Call external routines insert_frub and addfrub when a failure
  is found.
Call clean_up after a fru is reported to the controller.

RETURNS: NONE

Example Diagnostic Application Message File

$ COMPONENT_NAME: DAXYZ
$ FUNCTIONS: dxyz.msg - message file for screen display when diagnostic application dxyz is invoked.
$ Compilation: Use AIX command mkcatdefs to create header file containing symbols for use in C source code.
$ GENERAL NOTES FOR TRANSLATION PURPOSES
$ Do not translate %c, %d, %s, %x, %07X, or \t in any messages. They are used for word or number substitution and are noted in the comments for the individual messages. The $1, $2, $3, etc., within the substitutions are used to denote the order of the substitutions.
$ These comments concern the TITLE LINES at the top the diagnostic screen. The title must be in all capital letters. The first line of the title cannot be longer than 65 characters starting from column 1. If the line is greater than 65, it may be continued on the next line. Leave line spacing as shown: one blank line after the last title line. For example:
$ *****
$ TESTING PORT 12 OF THE 16-PORT ASYNCHRONOUS ADAPTER IN PLANAR SLOT 2
$ IN ADVANCED MODE
$ Please stand by.
$ *****
$ These comments concern the user ACTIONS in all caps. If translations require the creation of new lines, begin the new lines in the column immediately following the row of periods. For example:
$ *****
$ ACTION.........one line of English might require several when translated, so begin the next line at the same point of the previous line.
$ ACTION.........the next action follows with no blank line preceding it.
$ *****
$ The location of a resource is in the form of xx-xx-xx where x is an alpha-numeric character. The location is not translatable. It is an alpha-numeric descriptor of where the resource can be found.
$ END OF GENERAL NOTES
MSG1 "XYZ ADAPTER"
$ Leave line spacing as shown. See general notes on length of title line.
$set SRNS
$ Reason code set used by device type "XYZ"
R_XYZ_ADAPTER "An error was found on the adapter."
R_V35_CABLE "An error was found with the XYZ interface adapter cable."
R_ELA "Error log analysis indicates a hardware error."
R_DD "Adapter hardware has caused a software failure."
F_XYZ_DRAM "DRAM SIPs on the adapter card"
$ DRAM stands for Dynamic Random Access Memory. SIP stands for $ Single In-line Package.
CABLEFRU "Cable Part Number xxxxxxxx"

$set Q_PLUG_37_PIN
Q_PLUG_37_PIN_TITLE "TESTING XYZ ADAPTER IN ADVANCED MODE\n\nThe following test requires a 37 pin wrap plug, Part Number xxxxxxxx.\n\nDo you have this wrap plug?"
$ Check for appropriate part number in translating country.
$ Leave line spacing as shown. See general notes on length of title line.

Q_PLUG_37_PIN_YES "YES"
$ This option is shown when a YES answer is possible.

Q_PLUG_37_PIN_NO "NO"
$ This option is shown when a NO answer is possible.

Q_PLUG_37_PIN_ACTION "Move cursor to selection, then press Enter."
$ This message is shown when a multiple selection list is presented.
$set PLUG_37_PIN
$ PLUG_37_PIN_TITLE "TESTING XYZ ADAPTER IN ADVANCED MODE\n\nREMOVE.........the cable, if attached, from the adapter in\nl\n\nlocation %1$s.\n\n\nPLUG...........the wrap plug (Part Number xxxxxxxx) into\n\nthe adapter.\n\nWhen finished, press Enter."\n$ %1$s is the location of the adapter as described in the general notes.
$ See general notes on how to expand ACTION lines if necessary.
$ Check for appropriate part number in translating country.
$ Leave line spacing as shown. See general notes on length of title line.
$set UNPLUG_37_PIN
$ UNPLUG_37_PIN_TITLE "TESTING XYZ ADAPTER IN ADVANCED MODE\n\nUNPLUG............the wrap plug from the adapter.\n\nPLUG.............the interface cable, if it was removed, into the adapter.\n\nWhen finished, press Enter."\n$ This line instructs the user to restore things to the original state after testing is done.
$ See general notes on how to expand ACTION lines if necessary.
$ Leave line spacing as shown. See general notes on length of title line.
$set NO_RCM
$ NO_RCM_TITLE "902XXX\nXYZ OPERATIONAL MICROCODE IS MISSING\n\nThe XYZ operational microcode is either missing or not accessible.\n\n254 AIX Version 6.1 Understanding the Diagnostic Subsystem for AIX
This microcode is necessary in order to use the XYZ adapter card in normal system operations.

Leave line spacing as shown. See general notes on length of title. Do not translate the number 902XXX at the beginning of the message. Leave it exactly as shown.
## Chapter 8. Diagnostic Task Matrix

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

For license inquiries regarding double-byte (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:
IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

Any references in this information to non-IBM Web sites are provided for convenience only and do not in any manner serve as an endorsement of those Web sites. The materials at those Web sites are not part of the materials for this IBM product and use of those Web sites is at your own risk.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrates programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. You may copy, modify, and distribute these sample programs in any form without payment to IBM for the purposes of developing, using, marketing, or distributing application programs conforming to IBM's application programming interfaces.

Each copy or any portion of these sample programs or any derivative work, must include a copyright notice as follows:
(c) (your company name) (year). Portions of this code are derived from IBM Corp. Sample Programs. (c) Copyright IBM Corp. _enter the year or years_. All rights reserved.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurement may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Readers’ Comments — We’d Like to Hear from You

AIX Version 6.1
Understanding the Diagnostic Subsystem for AIX

Publication No. SC23-6602-00

We appreciate your comments about this publication. Please comment on specific errors or omissions, accuracy, organization, subject matter, or completeness of this book. The comments you send should pertain to only the information in this manual or product and the way in which the information is presented.

For technical questions and information about products and prices, please contact your IBM branch office, your IBM business partner, or your authorized remarketer.

When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute your comments in any way it believes appropriate without incurring any obligation to you. IBM or any other organizations will only use the personal information that you supply to contact you about the issues that you state on this form.

Comments:

Thank you for your support.
