Preliminary Information

Bt473

Distinguishing Features

- Bt471/478 Software Compatible
- 80, 66, 50, 35 MHz Operation
- Triple 8-bit D/A Converters
- Three 256 x 8 Color Palette RAMs
- Three 15 x 8 Overlay Registers
- RS-343A Compatible Outputs
- Sync on All Three Channels
- Programmable Pedestal(0 or 7.5 IRE)
- On-Chip Voltage Reference
- Standard MPU Interface
- +5 V CMOS Monolithic Construction
- 68-pin PLCC Package
- Typical Power Dissipation: 900 mW

Applications

- High-Resolution Color Graphics
- CAE/CAD/CAM
- Image Processing
- Instrumentation
- Desktop Publishing

80 MHz Monolithic CMOS Triple 8-bit True-Color RAMDAC™

4

Product Description

The Bt473 true-color RAMDAC is designed specifically for true-color computer graphics. It has three 256 x 8 color lookup tables with triple 8-bit video D/A converters to support 24-bit true-color operation. In addition, 8-bit pseudo- color, 8-bit true-color, and 15-bit true-color operations are supported.

Features include a programmable pedestal (0 or 7.5 IRE) and optional on-chip voltage reference. The 15 overlay registers provide for overlaying cursors, grids, menus, EGA emulation, etc. Also supported are a pixel read mask register and sync generation on all three channels.

Either an external current reference, an external voltage reference, or the internal voltage reference may be used.

The Bt473 generates RS-343A compatible video signals into a doubly terminated 75 Ω load. Differential and integral linearity errors are guaranteed to be a maximum of ±1 LSB over the full temperature range.

Functional Block Diagram

Brooktree®
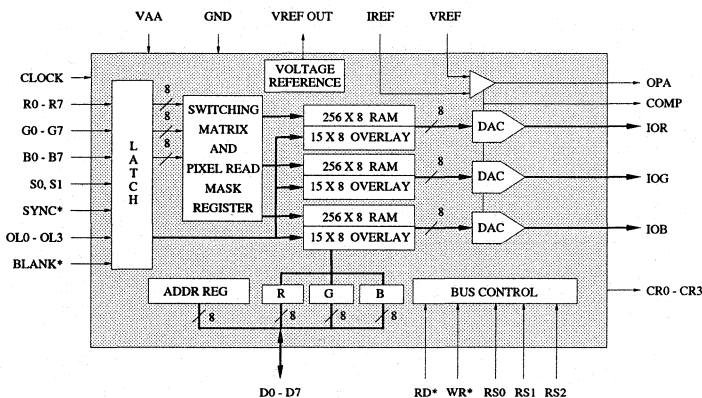

Circuit Description

MPU Interface

As illustrated in the functional block diagram, the Bt473 supports a standard MPU bus interface, allowing the MPU direct access to the color palette RAM and overlay color registers.

The RS0–RS2 select inputs specify whether the MPU is accessing the address register, color palette RAM, overlay registers, or read mask register, as shown in Table 1. The 8-bit address register is used to address the color palette RAM and overlay registers, eliminating the requirement for external address multiplexers. ADDR0 corresponds to D0 and is the least significant bit.

Writing Color Palette RAM Data

To write color data, the MPU writes the address register (RAM write mode) with the address of the color palette RAM location to be modified. The MPU performs three successive write cycles (8 bits each of red, green, and blue), using RS0–RS2 to select the color palette RAM. After the blue write cycle, the three bytes of color information are concatenated into a 24-bit word and written to the location specified by the address register. The address register then increments to the next location which the MPU may modify by simply writing another sequence of red, green, and blue data. A block of color values in consecutive locations may be written to by writing the start address and performing continuous R, G, B write cycles until the entire block has been written.

Reading Color Palette RAM Data

To read color palette RAM data, the MPU loads the address register (RAM read mode) with the address of the color palette RAM location to be read. The contents of the color palette RAM at the specified ad-

dress are copied into the RGB registers and the address register is incremented to the next RAM location. The MPU performs three successive read cycles (8 bits each of red, green, and blue), using RS0–RS2 to select the color palette RAM. Following the blue read cycle, the contents of the color palette RAM at the address specified by the address register are copied into the RGB registers and the address register again increments. A block of color values in consecutive locations may be read by writing the start address and performing continuous R, G, B read cycles until the entire block has been read.

Writing Overlay Color Data

To write overlay color data, the MPU writes the address register (overlay write mode) with the address of the overlay location to be modified. The MPU performs three successive write cycles (8 bits each of red, green, and blue), using RS0–RS2 to select the overlay registers. After the blue write cycle, the three bytes of color information are concatenated into a 24-bit word and written to the overlay location specified by the address register. The address register then increments to the next location, which the MPU may modify by simply writing another sequence of red, green, and blue data. A block of color values in consecutive locations may be written to by writing the start address and performing continuous R, G, B write cycles until the entire block has been written.

Reading Overlay Color Data

To read overlay color data, the MPU loads the address register (overlay read mode) with the address of the overlay location to be read. The contents of the overlay register at the specified address are copied

RS2	RS1	RS0	Addressed by MPU
0	0	0	address register (RAM write mode)
0	1	1	address register (RAM read mode)
0	0	1	color palette RAMs
0	1	0	pixel read mask register
1	0	0	address register (overlay write mode)
1	1	1	address register (overlay read mode)
1	0	1	overlay registers
1	1	0	command register

Table 1. Control Input Truth Table.

Circuit Description (continued)

into the RGB registers and the address register is incremented to the next overlay location. The MPU performs three successive read cycles (8 bits each of red, green, and blue), using RS0–RS2 to select the overlay registers. Following the blue read cycle, the contents of the overlay location at the address specified by the address register are copied into the RGB registers and the address register again increments. A block of color values in consecutive locations may be read by writing the start address and performing continuous R, G, B read cycles until the entire block has been read.

Additional Information

When accessing the color palette RAM, the address register resets to $00 following a blue read or write cycle to RAM location $FF. While accessing the overlay color registers, the 4 most significant bits of the address register (ADDR4–7) are ignored.

The MPU interface operates asynchronously to the pixel clock. Data transfers between the color palette RAM/overlay registers and the color registers (R, G, and B in the block diagram) are synchronized by internal logic, and occur in the period between MPU accesses. Occasional accesses to the color palette RAM can be made without noticeable disturbance on the display screen; however, operations requiring frequent access to the color palette (i.e., block fills of the color palette) should be done during the blanking interval.

To keep track of the red, green, and blue read/write cycles, the address register has 2 additional bits(ADDRa, ADDRb) that count modulo three, as shown in Table 2. They are reset to zero when the MPU writes to the address register, and are not reset to zero when the MPU reads the address register. The

MPU does not have access to these bits. The other 8 bits of the address register, incremented following a blue read or write cycle (ADDR0–7), are accessible to the MPU, and are used to address color palette RAM locations and overlay registers, as shown in Table 2. The MPU may read the address register at any time without modifying its contents or the existing read/write mode.

8-Bit / 6-Bit Operation

The command register specifies whether the MPU is reading and writing 8 bits or 6 bits of color information each cycle.

For 8-bit operation, D0 is the LSB and D7 is the MSB of color data.

For 6-bit operation, color data is contained on the lower 6 bits of the data bus, with D0 being the LSB and D5 the MSB of color data. When writing color data, D6 and D7 are ignored. During color read cycles, D6 and D7 will be a logical zero. Note that in the 6-bit mode, the Bt473's full-scale output current will be about 1.5% lower than when in the 8-bit mode. This is due to the 2 LSBs of each 8-bit DAC always being a logical zero in the 6-bit mode.

Color Modes

Four color modes are supported by the Bt473: 24-bit true color, 15-bit true color, 8-bit true color, and 8-bit pseudo color. The mode of operation is determined by the S0 and S1 inputs, in conjunction with CR7 and CR6 of the command register. S0 and S1 are pipelined to maintain synchronization with the R0–R7, G0–G7, B0–B7, and OL0–OL3 pixel and overlay data inputs.

Table 3 lists the modes of operation.

	Value	RS2	RS1	RS0	Addressed by MPU
ADDRa, b (counts modulo 3)	00	x	0	1	red value
	01	x	0	1	green value
	10	x	0	1	blue value

*Table 3. Color Operation Modes.*

Figure 1. MPU Read/Write Timing.

Circuit Description (continued)

24-Bit True-Color Mode

Twenty-four bits of RGB color information may be input into the Bt473 every clock cycle. The 24 bits of pixel information are input via the R0–R7, G0–G7, and B0–B7 inputs. R0–R7 address the red color palette RAM, G0–G7 address the green color palette RAM, and B0–B7 address the blue color palette RAM. Each RAM provides 8 bits of color information to the corresponding D/A converter. The pixel read mask register is used in this mode.

24-Bit True-Color Bypass Mode

Twenty-four bits of pixel information may be input into the Bt473 every clock cycle. The 24 bits of pixel information are input via the R0–R7, G0–G7, and B0–B7 inputs. R0–R7 drive the red DAC directly, G0–G7 drive the green DAC directly, and B0–B7 drive the blue DAC directly. The color palette RAMs and pixel read mask register are bypassed.

8-Bit Pseudo-Color Mode

Eight bits of pixel information may be input into the Bt473 every clock cycle. The 8 bits of pixel information (P0–P7) are input via the R0–R7, G0–G7 or B0–B7 inputs, as specified by CR7 and CR6. All three color palette RAMs are addressed by the same 8 bits of pixel data (P0–P7). Each RAM provides 8 bits of color information to the corresponding D/A converter. The pixel read mask register is used in this mode.

8-Bit True-Color Bypass Mode

Eight bits of pixel information may be input into the Bt473 every clock cycle. The 8 bits of pixel information are input via the R0–R7, G0–G7 or B0–B7 inputs, as specified by CR7 and CR6:

R0–R7 Inputs Selected	G0–G7 Inputs Selected	B0–B7 Inputs Selected	Input Format
R7	G7	B7	R7
R6	G6	B6	R6
R5	G5	B5	R5
R4	G4	B4	G7
R3	G3	B3	G6
R2	G2	B2	G5
R1	G1	B1	B7
R0	G0	B0	B6

As seen in the table, 3 bits of red, 3 bits of green, and 2 bits of blue data are input. The 3 MSBs of the red and green DACs are driven directly by the inputs, while the 2 MSBs of the blue DAC are driven directly by the inputs. The 5 LSBs for the red and green DACs, and the 6 LSBs for the blue DAC, are a logical zero. The color palette RAMs and pixel read mask register are bypassed.

15-Bit True-Color Bypass Mode

Fifteen bits of pixel information may be input into the Bt473 every clock cycle. The 15 bits of pixel information (5 bits of red, 5 bits of green, and 5 bits of blue) are input via the R0–R7 and G0–G7 inputs:

Pixel Inputs	Input Format
R7	0
R6	R7
R5	R6
R4	R5
R3	R4
R2	R3
R1	G7
R0	G6
G7	G5
G6	G4
G5	G3
G4	B7
G3	B6
G2	B5
G1	B4
G0	B3

The 5 MSBs of the red, green, and blue DACs are driven directly by the inputs. The 3 LSBs are a logical zero. The color palette RAMs and pixel read mask register are bypassed.

Overlays

The overlay inputs, OL0–OL3, have priority regardless of the color mode, as shown in Table 3.

Circuit Description (continued)

Pixel Read Mask Register

The 8-bit pixel read mask register is implemented as three 8-bit pixel read mask registers, one each for the R0–R7, G0–G7, and B0–B7 inputs. When writing to the pixel read mask register, the same data is written to all three registers. The read mask registers are located just before the color palette RAMs. Thus, they are used only in the 24-bit true-color and 8-bit pseudo-color modes since these are the only modes that use the color palette RAMs.

The contents of the pixel read mask register, which may be accessed by the MPU at any time, are bit-wise logically ANDed with the 8-bit inputs prior to addressing the color palette RAMs. Bit D0 of the pixel read mask register corresponds to pixel input P0 (R0, G0, or B0 depending on the mode). Bit D0 also corresponds to data bus bit D0. This register is not initialized. It must be initialized by the user after power-up for proper operation.
Programmable Setup

The command register specifies whether a 0 IRE or 7.5 IRE blanking pedestal is to be used.

Video Generation

The SYNC* and BLANK* inputs, also latched on the rising edge of CLOCK to maintain synchronization with the color data (see figure 2), add appropriately weighted currents to the analog outputs, producing the specific output levels required for video applications, as illustrated in Figures 3 and 4. Tables 4 and 5 detail how the SYNC* and BLANK* inputs modify the output levels.

The analog outputs of the Bt473 are capable of directly driving a 37.5 Ω load, such as a doubly terminated 75 Ω coaxial cable.

Internal Registers

Command Register

The command register may be written to or read by the MPU at any time, and is not initialized. For proper operation, it must be initialized by the user after power-up. CR0 is the least significant bit and corresponds to D0.

CR7, CR6   Color mode select   These bits are used to control the various color modes, as shown in Table 3.

CR5   Setup select   Used to specify either a 0 IRE (logical zero) or 7.5 IRE (logical one) blanking pedestal.

              (0) 0 IRE
              (1) 7.5 IRE

CR4   8-bit / 6-bit color select   This bit specifies whether the MPU is reading and writing 8 bits (logical one) or 6 bits (logical zero) of color information each cycle. For 8-bit operation, D7 is the most significant data bit during color read/write cycles. For 6-bit operation, D5 is the most significant data bit during color read/write cycles (D6 and D7 are ignored during color write cycles and a logical zero during color read cycles).

              (0) 6-bit
              (1) 8-bit

CR3–CR0   CR3–CR0 outputs   These bits are output onto the CR3–CR0 pins.
Pin Descriptions

Pin Name	Description
BLANK*	Composite blank control input (TTL compatible). A logic zero drives the analog outputs to the blanking level, as illustrated in Tables 4 and 5. It is latched on the rising edge of CLOCK. When BLANK* is a logical zero, the pixel and overlay inputs are ignored.
SYNC*	Composite sync control input (TTL compatible). A logical zero on this input switches off a 40 IRE current source on the analog outputs (see Figures 3 and 4). SYNC* does not override any other control or data input, as shown in Tables 4 and 5; therefore, it should be asserted only during the blanking interval. It is latched on the rising edge of CLOCK. If sync information is not to be generated on the analog outputs, this pin should be connected to GND.
CLOCK	Clock input (TTL compatible). The rising edge of CLOCK latches the R0–R7, G0–G7, B0–B7, S0, S1, OL0–OL3, SYNC*, and BLANK* inputs. It is typically the pixel clock rate of the video system. It is recommended that CLOCK be driven by a dedicated TTL buffer to avoid reflection-induced jitter. Refer to the PC Board Layout Considerations section for critical layout criteria.
R0–R7, G0–G7, B0–B7	Red, green, and blue pixel select inputs (TTL compatible). These inputs specify, on a pixel basis, which one of the 256 entries in the red, green, and blue color palette RAMs is to be used to provide color information. They are latched on the rising edge of CLOCK. R0, G0, and B0 are the LSBs. Unused inputs should be connected to GND.
S0, S1	Color mode select inputs (TTL compatible). These inputs specify the mode of operation as shown in Table 3. They are latched on the rising edge of CLOCK.
OL0–OL3	Overlay select inputs (TTL compatible). These inputs specify which palette is to be used to provide color information, as illustrated in Table 3. When accessing the overlay palette, the R0–R7, G0–G7, B0–B7, S0, and S1 inputs are ignored. They are latched on the rising edge of CLOCK. OL0 is the LSB. Unused inputs should be connected to GND.
IOR, IOG, IOB	Red, green, and blue current outputs. These high-impedance current sources are capable of directly driving a doubly terminated 75 Ω coaxial cable (Figures 5, 6, and 7).
IREF	When using a voltage reference (Figures 5 and 6), a resistor (RSET) connected between this pin and GND controls the magnitude of the full-scale video signal. The relationship between RSET and the full-scale output current on each output is: $$\text{for SETUP} = 7.5 \text{ IRE:} \quad \text{RSET } (\Omega) = 3,195 * \text{VREF (V) / Iout (mA)}$$ $$\text{for SETUP} = 0 \text{ IRE:} \quad \text{RSET } (\Omega) = 3,025 * \text{VREF (V) / Iout (mA)}$$ When using an external current reference (Figure 7), the relationship between IREF and the full-scale output current on each output is: $$\text{for SETUP} = 7.5 \text{ IRE:} \quad \text{IREF (mA)} = \text{Iout (mA) / 3.195}$$ $$\text{for SETUP} = 0 \text{ IRE:} \quad \text{IREF (mA)} = \text{Iout (mA) / 3.025}$$

Pin Descriptions *(continued)*

Pin Name	Description
COMP	Compensation pin. If an external voltage reference is used (Figures 5 and 6), this pin should be connected to OPA. If an external current reference is used (Figure 7), this pin should be connected to IREF. A 0.1 µF ceramic capacitor must always be used to bypass this pin to VAA. The COMP capacitor must be as close to the device as possible to keep lead lengths to an absolute minimum. *Refer to PC Board Layout Considerations for critical layout criteria.*
VREF	Voltage reference input. If a voltage reference is used (Figures 5 and 6), it must supply this input with a 1.2 V (typical) reference. If an external current reference is used (Figure 7), this pin should be left floating, except for the bypass capacitor. A 0.1 µF ceramic capacitor is used to decouple this input to GND, as shown in Figures 5 and 6. The decoupling capacitor must be as close to the device as possible to keep lead lengths to an absolute minimum. Refer to the PC Board Layout Considerations section for critical layout criteria.
OPA	Reference amplifier output. If a voltage reference is used (Figures 5 and 6), this pin must be connected to COMP. When using an external current reference (Figure 7), this pin should be left floating.
VREF OUT	Voltage reference output. This output provides a 1.2 V (typical) reference, and may be connected directly to the VREF pin. If the on-chip reference is not used, this pin may be left floating. See Figures 5 and 6. Up to four Bt473s may be driven by this output.
VAA	Analog power. All VAA pins must be connected together on the same PCB plane to prevent latchup. Refer to the PC Board Layout Considerations section for critical layout criteria.
GND	Analog ground. All GND pins must be connected together on the same PCB plane to prevent latchup. Refer to the PC Board Layout Considerations section for critical layout criteria.
WR*	Write control input (TTL compatible). D0–D7 data is latched on the rising edge of WR*, and RS0–RS2 are latched on the falling edge of WR* during MPU write operations. RD* and WR* should not be asserted simultaneously. See Figures 1 and 8.
RD*	Read control input (TTL compatible). To read data from the device, RD* must be a logical zero. RS0–RS2 are latched on the falling edge of RD* during MPU read operations. RD* and WR* should not be asserted simultaneously. See Figures 1 and 8.
RS0, RS1, RS2	Register select inputs (TTL compatible). RS0–RS2 specify the type of read or write operation being performed, as illustrated in Tables 1 and 2.
D0–D7	Data bus (TTL compatible). Data is transferred into and out of the device over this 8-bit bidirectional data bus. D0 is the least significant bit.
CR0–CR3	Control outputs (TTL compatible). These outputs are used to control application-specific features. The output values are determined by the command register. See Figure 8.

PC Board Layout Considerations

PC Board Considerations

For optimum performance of the Bt473, proper CMOS RAMDAC layout techniques should be studied in the Bt451/7/8 Evaluation Module Operation and Measurements, Application Note (AN-16), before PC board layout is begun. This application note can be found in Brooktree's *Applications Handbook*.

The layout should be optimized for lowest noise on the Bt473 power and ground planes by providing good decoupling. The trace length between groups of VAA and GND pins should be as short as possible to minimize inductive ringing.

A well-designed power distribution network is critical to eliminating digital switching noise. The ground plane must provide a low-impedance return path for the digital circuits. A PC board with a minimum of four layers is recommended, with layers 1 (top) and 4 (bottom) for signals and layers 2 and 3 for power and ground.

Component Placement

Components should be placed as close as possible to the associated RAMDAC pin. Whenever possible, components should be placed so traces can be connected point to point.

The optimum layout enables the Bt473 to be located as close as possible to the power supply connector and the video output connector.

Ground Planes

For optimum performance, a common digital and analog ground plane is recommended.

Power Planes

Separate digital and analog power planes are recommended. The digital power plane should provide power to all digital logic on the PC board, and the analog power plane should provide power to all Bt473 power pins, VREF circuitry, and COMP and VREF decoupling. There should be at least a 1/8-inch gap between the digital power plane and the analog power plane.

The analog power plane should be connected to the digital power plane (VCC) at a single point through a ferrite bead, as illustrated in Figures 5, 6, and 7. This bead should be located within 3 inches of the Bt473. The bead provides resistance to switching currents, acting as a resistance at high frequencies. A low-resistance bead should be used, such as Ferroxcube 5659065-3B, Fair-Rite 2743001111, or TDK BF45-4001.

Device Decoupling

For optimum performance, all capacitors should be located as close as possible to the device, and the shortest possible leads (consistent with reliable operation) should be used to reduce the lead inductance. Chip capacitors are recommended for minimum lead inductance. Radial lead ceramic capacitors may be substituted for chip capacitors and are better than axial lead capacitors for self-resonance. Values are chosen to have self-resonance above the pixel clock.

Power Supply Decoupling

The best power supply decoupling performance is obtained with a 0.1 µF ceramic capacitor, decoupling each of the two groups of VAA pins to GND. For operation above 75 MHz, a 0.1 µF capacitor in parallel with a 0.01 µF chip capacitor is recommended. The capacitors should be placed as close as possible to the device VAA and GND pins and connected with short, wide traces.

The 10 µF capacitor shown in Figures 5, 6, and 7 is for low-frequency power supply ripple; the 0.1 µF capacitors are for high-frequency power supply noise rejection.

When a linear regulator is used, the power-up sequence must be verified to prevent latchup. A linear regulator is recommended to filter the analog power supply if the power supply noise is greater than or equal to 200 mV. This is especially important when a switching power supply is used, and the switching frequency is close to the raster scan frequency. About 10 percent of the power supply hum and ripple noise less than 1 MHz will couple onto the analog outputs.

COMP Decoupling

The COMP pin must be decoupled to VAA, typically with a 0.1 µF ceramic capacitor. Low-frequency supply noise will require a larger value. The COMP capacitor must be as close as possible to the COMP and VAA pins. A surface-mount ceramic chip capacitor is preferred for minimal lead inductance. Lead inductance degrades the noise rejection of the circuit. Short, wide traces will also reduce lead inductance.

If the display has a ghosting problem, additional capacitance in parallel with the COMP capacitor may help.

VREF Decoupling

A 0.1 µF ceramic capacitor should be used to decouple this input to GND.

PC Board Layout Considerations (continued)

Digital Signal Interconnect

The digital inputs to the Bt473 should be isolated as much as possible from the analog outputs and other analog circuitry. Also, these input signals should not overlay the analog power plane or analog output signals.

Most of the noise on the analog outputs will be caused by excessive edge rates (less than 3 ns), overshoot, undershoot, and ringing on the digital inputs.

The digital edge rates should not be faster than necessary, as feedthrough noise is proportional to the digital edge rates. Lower-speed applications will benefit from using lower-speed logic (3–5 ns edge rates) to reduce data-related noise on the analog outputs.

Transmission lines will mismatch if the lines do not match the source and destination impedance. This will degrade signal fidelity if the line length reflection time is greater than one fourth the signal edge time (refer to Brooktree Application Notes AN-11 and AN-12). Line termination or line-length reduction is the solution. For example, logic edge rates of 2 ns require line lengths of less than 4 inches without use of termination. Ringing may be reduced by damping the line with a series resistor (30–300 Ω). The RS-select inputs and RD*/WR* lines must be verified for proper levels with no ringing, undershoot, or overshoot. Ringing on these lines can cause improper operation.

Radiation of digital signals can also be picked up by the analog circuitry. This is prevented by reducing the digital edge rates (rise/fall time), minimizing ringing with damping resistors, and minimizing coupling through PC board capacitance by routing the digital signals at a 90 degree angle to any analog signals.

The clock driver and all other digital devices must be adequately decoupled to prevent noise generated by the digital devices from coupling into the analog circuitry.

Clock Interfacing

The Bt473 requires a pixel clock with monotonic clock edges for proper operation. Impedance mismatch on the pixel clock line will induce reflections on the pixel clock, which may cause erratic operation.

The Pixel Clock Pulse Width High Time and Pixel Clock Pulse Width Low Time minimum specifications (see the AC Characteristics section) must not be violated, or erratic operation can occur.

The pixel clock line must be terminated to prevent impedance mismatch. A series termination of 33–68 Ω placed at the pixel clock driver may be used, or a parallel termination may be used at the pixel clock input to the RAMDAC. A parallel termination of 220 Ω to VCC and 330 Ω to ground will provide a Thevenin

equivalent of a 110 Ω termination, which is normally sufficient to absorb reflections. The series or parallel resistor values should be adjusted to provide the optimum clock signal fidelity.

MPU Control Signal Interfacing

The Bt473 uses the RD*, WR*, and RS lines to determine which MPU accesses will take place. Glitches or ringing on any of these lines may cause improper MPU operation. When a VGA controller with edge rate control is used on these lines, a series termination is not necessary. In non-VGA controller application or in applications where the MPU control signals are daisy chained, a series termination, pull-down resistors, or additional capacitance to ground should be used to prevent glitches that could cause improper MPU accesses.

Analog Signal Interconnect

The Bt473 should be located as close as possible to the output connectors to minimize noise pickup and reflections caused by impedance mismatch.

The analog outputs are susceptible to crosstalk from digital lines; digital traces must not be routed under or adjacent to the analog output traces.

To maximize the high-frequency power supply rejection, the video output signals should not overlay the analog power plane.

For maximum performance, the analog video output impedance, cable impedance, and load impedance should be the same. The load resistor connection between the video outputs and GND should be as close as possible to the Bt473 to minimize reflections. Unused analog outputs should be connected to GND.

Analog output video edges exceeding the CRT monitor bandwidth can be reflected, producing cable-length dependent ghosts. Simple pulse filters can reduce high-frequency energy, reducing EMI and noise. The filter impedance must match the line impedance.

Analog Output Protection

The Bt473 analog output should be protected against high-energy discharges, such as those from monitor arc-over or from hot-switching AC-coupled monitors.

The diode protection circuit shown in Figures 5, 6, and 7 can prevent latchup under severe discharge conditions without adversely degrading analog transition times. The 1N4148/9 parts are low-capacitance, fast-switching diodes, which are also available in multiple-device packages (FSA250X or FSA270X) or surface-mountable pairs (BAV99 or MMBD7001).

PC Board Layout Considerations *(continued)*
Note: For operation above 75 MHz, each pair of device VAA and GND pins must be separately decoupled with 0.1 µF and 0.01 µF capacitors.

Application Information

Using Multiple Devices

When using multiple Bt473s, each Bt473 should have its own power plane ferrite bead.

Although the VREF OUT of a Bt473 may drive up to four Bt473s, higher performance may be obtained if each RAMDAC uses its own reference. This will reduce the amount of color channel crosstalk and color palette interaction.

Each Bt473 must still have its own individual RSET resistor, analog output termination resistors, power supply bypass capacitors, COMP capacitor, and reference capacitors.

Reference Selection

An external voltage reference provides about 10x better power supply rejection on the analog outputs than an external current reference.

ESD and Latchup Considerations

Correct ESD-sensitive handling procedures are required to prevent device damage, which can produce symptoms of catastrophic failure or erratic device behavior with somewhat "leaky" inputs.

All logic inputs should be held low until power to the device has settled to the specified tolerance. Avoid DAC power decoupling networks with large time constants, which could delay VAA power to the device. Ferrite beads must only be used for analog power VAA decoupling. Inductors cause a time constant delay that induces latchup.

Latchup can be prevented by assuring that all VAA pins are at the same potential, and that the VAA supply voltage is applied before the signal pin voltages. The correct power-up sequence assures that any signal pin voltage will never exceed the power supply voltage by more than +0.5 V.

Recommended Operating Conditions

Parameter	Symbol	Min	Typ	Max	Units
Power Supply	VAA				
80, 66 MHz Parts		4.75	5.00	5.25	V
50, 35 MHz Parts		4.5	5.00	5.5	V
Ambient Operating Temperature	TA	0		+70	°C
Output Load	RL		37.5		Ω
Voltage Reference Configuration					
Reference Voltage	VREF	1.14	1.235	1.26	V
Current Reference Configuration					
IREF Current	IREF				
Standard RS-343A		–3	–8.39	–10	mA
PS/2 Compatible		–3	–8.88	–10	mA

4

Absolute Maximum Ratings

Parameter	Symbol	Min	Typ	Max	Units
VAA (measured to GND)				7.0	V
Voltage on Any Signal Pin (Note 1)		GND–0.5		VAA + 0.5	V
Analog Output Short Circuit Duration to Any Power Supply or Common	ISC		indefinite		
Ambient Operating Temperature	TA	–55		+125	°C
Storage Temperature	TS	–65		+150	°C
Junction Temperature	TJ			+150	°C
Vapor Phase Soldering (1 minute)	TVSOL			220	°C

Note: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Note 1: This device employs high-impedance CMOS devices on all signal pins. It should be handled as an ESD-sensitive device. Voltage on any signal pin that exceeds the power supply voltage by more than +0.5 V can induce destructive latchup.

DC Characteristics

Parameter	Symbol	Min	Typ	Max	Units
Resolution (each DAC)		8	8	8	Bits
Accuracy (each DAC)					
Integral Linearity Error	IL			±1	LSB
Differential Linearity Error	DL			±1	LSB
Gray Scale Error					
Using External Reference				±5	% Gray Scale
Using Internal Reference				±10	% Gray Scale

Power Supply Rejection Ratio (Note 1)	PSRR			0.5	% / % ΔVAA
(COMP = 0.1 µF, f = 1 KHz)					

Test conditions to generate RS-343A standard video signals (unless otherwise specified): "Recommended Operating Conditions" using external voltage reference with RSET = 140 Ω, VREF = 1.235 V. As the above parameters are guaranteed over the full temperature range, temperature coefficients are not specified or required. Typical values are based on nominal temperature, i.e., room temperature, and nominal voltage, i.e., 5 V.

Note: When using the internal voltage reference, RSET may need to be adjusted to meet these limits. Also, the "gray-scale" output current (white level relative to black) will have a typical tolerance of ±10% rather than the ±5% specified above.

Note 1: Guaranteed but not tested.

Analog Output Levels — PS/2 Compatibility

Parameter	Symbol	Min	Typ	Max	Units
Analog Outputs					
Output Current					
White Level Relative to Black		18.00	18.65	20.00	mA
Black Level Relative to Blank					
SETUP = 7.5 IRE		1.01	1.51	2.0	mA
SETUP = 0 IRE		0	5	50	µA
Blank Level		6.6	8	9.4	mA
Sync Level		0	5	50	µA

Test conditions to generate PS/2 compatible video signals (unless otherwise specified): "Recommended Operating Conditions" using external voltage reference with RSET = 140 Ω, VREF = 1.235 V or external current reference with IREF = –8.88 mA.

Test conditions (unless otherwise specified): "Recommended Operating Conditions" using external voltage reference with RSET = 140 Ω, VREF = 1.235 V. TTL input values are 0–3 V, with input rise/fall times ≤ 4 ns, measured between the 10-percent and 90-percent points. Timing reference points at 50 percent for inputs and outputs. Analog output load ≤ 10 pF, D0–D7 output load ≤ 75 pF. See timing notes in Figure 9. As the above parameters are guaranteed over the full temperature range, temperature coefficients are not specified or required. Typical values are based on nominal temperature, i.e., room temperature, and nominal voltage, i.e., 5 V.

Note 1: Clock and data feedthrough is a function of the amount of edge rates, overshoot, and undershoot on the digital inputs. For this test, the digital inputs have a 1 kΩ resistor to ground and are driven by 74HC logic. Settling time does not include clock and data feedthrough. Glitch impulse includes clock and data feedthrough, –3 dB test bandwidth = 2x clock rate.

Note 2: At Fmax. IAA (typ) at VAA = 5.0 V. IAA (max) at VAA (max).
Timing Waveforms

Figure 8. MPU Read/Write Timing.

Note 1: Output delay is measured from the 50-percent point of the rising edge of CLOCK to the 50-percent point of full-scale transition.

Note 2: Settling time is measured from the 50-percent point of full-scale transition to the output remaining within ±1 LSB.

Note 3: Output rise/fall time is measured between the 10-percent and 90-percent points of full-scale transition.

Figure 9. Video Input/Output Timing.
